Access exceptions for the portion of the first or second operand to the right of the last character processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last character processed.

Access exceptions for all characters of the translation table may be recognized even if not all characters are used.

Access exceptions are not recognized if the R<sub>1</sub> field is odd. When the length of the second operand is zero, no access exceptions for the first or second operand are recognized, and access exceptions for the translation table may or may not be recognized.

#### ***Resulting Condition Code:***

- 0 Entire second operand processed; if test-character comparison was performed, no resulting function character was equal to the test character
- 1 Second-operand character found resulting in a function character equal to the test character (applicable only when test-character comparison is performed)
- 2 --
- 3 CPU-determined number of characters processed

#### ***Program Exceptions:***

- Access (fetch, operand 2 and translation table; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification

#### ***Programming Notes:***

1. These instructions differ from the TRANSLATE EXTENDED instruction by having the following attributes:
  - Depending on the instruction used, the sets of argument characters and function characters each can contain single-byte or double-byte characters.
  - The test character is compared to a resulting function character instead of to an argument character.
  - The argument (source) and function (destination) operands are different operands.
2. When condition code 3 is set, the program can simply branch back to the instruction to continue the translation. The program need not determine the number of characters that were translated.
3. The storage operand references of these instructions may be multiple-access references. (See "Storage-Operand Consistency" on page 5-95.)

## **UNPACK**

UNPK	D <sub>1</sub> (L <sub>1</sub> ,B <sub>1</sub> ),D <sub>2</sub> (L <sub>2</sub> ,B <sub>2</sub> )	[SS]
'F3'	L <sub>1</sub> L <sub>2</sub> B <sub>1</sub> D <sub>1</sub> B <sub>2</sub> D <sub>2</sub>	0 8 12 16 20 32 36 47

The format of the second operand is changed from signed-packed-decimal to zoned, and the result is placed at the first-operand location. The signed-packed-decimal and zoned formats are described in Chapter 8, "Decimal Instructions."

The second operand is treated as having the signed-packed-decimal format. Its digits and sign are placed unchanged in the first-operand location, using the zoned format. Zone bits with coding of 1111 are supplied for all bytes except the rightmost byte, the zone of which receives the sign of the second operand. The sign and digits are not checked for valid codes.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros. If the first-operand field is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the operands overlap, the result is obtained as if the operands were processed one byte at a time and as if the first result byte were stored immediately after fetching the first operand byte. The entire rightmost second-operand byte is used in forming the first result byte. For the remainder of the field, information for two result bytes is obtained from a single second-operand byte, and execution proceeds as if the leftmost four bits of the byte were to remain available for the next result byte and need not be refetched. Thus, the result is as if two result bytes were to be stored immediately after fetching a single operand byte.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Access (fetch, operand 2; store, operand 1)

#### Programming Notes:

1. An example of the use of the UNPACK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. A field that is to be unpacked can be destroyed by improper overlapping. To save storage space for unpacking by overlapping the operands, the rightmost byte of the first operand must be to the right of the rightmost byte of the second operand by the number of bytes in the second operand minus 2. If only one or two bytes are to be unpacked, the rightmost bytes of the two operands may coincide.
3. The storage-operand references of UNPACK may be multiple-access references. (See “Storage-Operand Consistency” on page 5-95.)

## UNPACK ASCII

UNPKA	D <sub>1</sub> (L <sub>1</sub> ,B <sub>1</sub> ),D <sub>2</sub> (B <sub>2</sub> )	[SS]
'EA'	L <sub>1</sub>	B <sub>1</sub>
0	8	16 20 32 36 47

The format of the second operand is changed from signed-packed-decimal to ASCII, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the signed-packed-decimal format. Its digits are converted to ASCII characters by extending them on the left with 0011 binary, and the ASCII characters are then placed at the first operand location. The digits are not checked for valid codes.

The sign of the second operand is not transferred to the first operand but is checked for validity and determines the condition code. If the sign is 1010, 1100, 1110 or 1111 binary (plus), condition code 0 is set. If the sign is 1011 or 1101 binary (minus), condition code 1 is set. If the sign is not one of the codes for plus or minus, condition code 3 is set.

The converted last digit is placed in the rightmost byte position of the result field, and the other converted digits are placed adjacent to the last and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left.

The length of the second operand is 16 bytes. The second operand consists of 31 digits and a sign.

The length of the first operand is designated by the contents of the L<sub>1</sub> field. The first-operand length must not exceed 32 bytes (L<sub>1</sub> must be less than or equal to 31); otherwise, a specification exception is recognized.

If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the length of the first operand is 32 bytes, the leftmost byte is set to ASCII zero, 30 hex.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first operand is not necessarily stored into in any particular order.

**Resulting Condition Code:**

- 0 Sign is plus
- 1 Sign is minus
- 2 --
- 3 Sign is invalid

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification

**Programming Note:**

1. The following example illustrates the use of the instruction to unpack to ASCII digits:

```

ASDIGITS DS CL31
PKDIGITS DS 0PL16
      DC X'1234567890'
      DC X'1234567890'
      DC X'1234567890'
      DC X'1C'
      :
UNPKA ASDIGITS(31),PKDIGITS

```

2. The storage-operand references of UNPACK ASCII may be multiple-access references. (See "Storage-Operand Consistency" on page 5-95.)
3. The UNPACK ASCII and UNPACK UNICODE instructions set condition code 0 to indicate a positive sign, and these instructions provide no indication of a zero result. In all other instructions that indicate a signed result, condition code 0 indicates a result of zero, and condition code 2 indicates a positive result.

**UNPACK UNICODE**

UNPKU	D <sub>1</sub> (L <sub>1</sub> ,B <sub>1</sub> ),D <sub>2</sub> (B <sub>2</sub> )	[SS]
'E2'	L <sub>1</sub>	B <sub>1</sub>

D<sub>1</sub>      D<sub>2</sub>

0            8            16            20            32            36            47

The format of the second operand is changed from signed-packed-decimal to Unicode Basic Latin, and the result is placed at the first-operand location. The

signed-packed-decimal format is described in Chapter 8, "Decimal Instructions."

The second operand is treated as having the signed-packed-decimal format. Its digits are converted to two-byte Unicode characters by extending them on the left with 000000000011 binary (003 hex), and the Unicode characters are then placed at the first operand location. The digits are not checked for valid codes. The sign of the second operand is not transferred to the first operand but is checked for validity and determines the condition code. If the sign is 1010, 1100, 1110 or 1111 binary (plus), condition code 0 is set. If the sign is 1011 or 1101 binary (minus), condition code 1 is set. If the sign is not one of the codes for plus or minus, condition code 3 is set.

The converted last digit is placed in the rightmost character position of the result field, and the other converted digits are placed adjacent to the last and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left.

The length of the second operand is 16 bytes; the second operand consists of 31 digits and a sign.

The length of the first operand is designated by the contents of the L<sub>1</sub> field. The first-operand length must not exceed 32 characters or 64 bytes (L<sub>1</sub> must be less than or equal to 63 and must be odd); otherwise a specification exception is recognized.

If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the length of the first operand is 32 characters, the leftmost character is set to Unicode Basic Latin zero, 0030 hex.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first operand is not necessarily stored into any particular order.

**Resulting Condition Code:**

- 0 Sign is plus
- 1 Sign is minus
- 2 --
- 3 Sign is invalid

**Program Exceptions:**

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification

**Programming Notes:**

1. The following example illustrates the use of the instruction to unpack to European numbers:

```

UNDIGITS DS CL62
PKDIGITS DS OPL16
DC X'1234567890'
DC X'1234567890'
DC X'1234567890'
DC X'1C'
UNPKU UNDIGITS(62),PKDIGITS

```

2. The storage-operand references of UNPACK UNICODE may be multiple-access references. (See "Storage-Operand Consistency" on page 5-95.)
3. The UNPACK ASCII and UNPACK UNICODE instructions set condition code 0 to indicate a positive sign, and these instructions provide no indication of a zero result. In all other instructions that indicate a signed result, condition code 0 indicates a result of zero, and condition code 2 indicates a positive result.

**UPDATE TREE**

UPT	[E]
'0102'	
0	15

The nodes of a tree in storage are examined successively on a path toward the base of the tree, and contents of general register 0, conceptually followed on the right by contents of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in general register 0. The first half of a node and general

register 0 contain a codeword, which is for use in sort/merge algorithms.

If the codeword in general register 0 equals the codeword in a node, the contents of the node are placed in general registers 2 and 3.

General register 4 contains the base address of the tree, and general register 5 contains the index of a node whose parent node will be examined first.

In the access-register mode, access register 4 specifies the address space containing the tree.

This instruction may be interrupted between units of operation. The condition code is unpredictable if the instruction is interrupted.

The size of a node, the size of a codeword, and the participation of bits 0-31 of general registers 1-5 in the operation depend on the addressing mode. In the 24-bit or 31-bit addressing mode, a node is eight bytes, a codeword is four bytes, and bits 0-31 are ignored and remain unchanged. In the 64-bit addressing mode, a node is 16 bytes, a codeword is eight bytes, and bits 0-31 are used in and may be changed by the operation.

**Operation in the 24-Bit or 31-Bit Addressing Mode**

In the 24-bit or 31-bit addressing mode, the double-word nodes of a tree in storage are examined successively on a path toward the base of the tree, and the contents of bit positions 32-63 of general register 0, conceptually followed on the right by the contents of bit positions 32-63 of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in bit positions 32-63 of general register 0.

Bit positions 32-63 of general register 4 contain the base address of the tree, and bit positions 32-63 of general register 5 contain the index of a node whose parent node will be examined first. The base address is eight less than the address of the root node of the tree. The initial contents of bit positions 32-63 of general registers 4 and 5 must be a multiple of 8; otherwise, a specification exception is recognized.

A unit of operation begins by shifting the contents of bit positions 32-63 of general register 5 right logically one position and then setting bit 61 to zero. However, bits 32-63 of general register 5 remain unchanged if

the execution of a unit of operation is nullified or suppressed. If after shifting and setting bit 61 to zero, bits 32-63 of general register 5 are all zeros, the instruction is completed, and condition code 1 is set; otherwise, the unit of operation continues.

Bit 32 of general register 0 is tested. If bit 32 of general register 0 is one, the instruction is completed, and condition code 3 is set.

If bit 32 of general register 0 is zero, the sum of bits 32-63 of general registers 4 and 5 is used as the intermediate value for normal operand address generation. The generated address is the address of a node in storage.

Bits 32-63 of general register 0 are logically compared with the contents of the first word of the currently addressed node. If the register operand is low, the contents of bit positions 32-63 of general registers 0 and 1 are interchanged with those of the node, and a unit of operation is completed. If the register operand is high, no additional action is taken, and the unit of operation is completed. If the compare values are equal, bit positions 32-63 of general register 2, conceptually followed on the right by bit positions 32-63 of general register 3, are loaded from the currently addressed node, the instruction is completed, and condition code 0 is set.

In those cases when the value in the first word of the node is less than or equal to the value in bit positions 32-63 of the register, the contents of the node remain unchanged. However, in some models, these contents may be fetched and subsequently stored back.

### **Operation in the 64-Bit Addressing Mode**

In the 64-bit addressing mode, the quadword nodes of a tree in storage are examined successively on a path toward the base of the tree, and the contents of general register 0, conceptually followed on the right by the contents of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in general register 0.

General register 4 contains the base address of the tree, and general register 5 contain the index of a node whose parent node will be examined first. The base address is 16 less than the address of the root

node of the tree. The initial contents of general registers 4 and 5 must be a multiple of 16; otherwise, a specification exception is recognized.

A unit of operation begins by shifting the contents of general register 5 right logically one position and then setting bit 60 to zero. However, general register 5 remains unchanged if the execution of a unit of operation is nullified or suppressed. If after shifting and setting bit 60 to zero, the contents of general register 5 are zero, the instruction is completed, and condition code 1 is set; otherwise, the unit of operation continues.

Bit 0 of general register 0 is tested. If bit 0 of general register 0 is one, the instruction is completed, and condition code 3 is set.

If bit 0 of general register 0 is zero, the sum of the contents of general registers 4 and 5 is used as the intermediate value for normal operand address generation. The generated address is the address of a node in storage.

The contents of general register 0 are logically compared with the contents of the first doubleword of the currently addressed node. If the register operand is low, the contents of general registers 0 and 1 are interchanged with those of the node, and a unit of operation is completed. If the register operand is high, no additional action is taken, and the unit of operation is completed. If the compare values are equal, general registers 2 and 3 are loaded from the currently addressed node, the instruction is completed, and condition code 0 is set.

In those cases when the value in the first doubleword of the node is less than or equal to the value in the register, the contents of the node remain unchanged. However, in some models, these contents may be fetched and subsequently stored back.

### **Specifications Independent of Addressing Mode**

Access exceptions are recognized only for one node at a time. Access exceptions, change-bit action, and PER storage alteration do not occur for subsequent nodes until the previous node has been successfully compared and updated, and they also do not occur if a specification-exception condition exists.

**Resulting Condition Code:**

- 0 Equal compare values at currently addressed node
- 1 No equal compare values found on path, or no comparison made
- 2 --
- 3 In 24-bit or 31-bit mode, bits 32-63 of general register 5 nonzero and bits 32-63 of general register 0 negative; in 64-bit mode, general register 5 nonzero and general register 0 negative

**Program Exceptions:**

- Access (fetch and store, nodes of tree)
- Specification

**Programming Notes:**

1. An example of the use of UPDATE TREE is given in "Sorting Instructions" in Appendix A, "Number Representation and Instruction-Use Examples."
2. For use in sorting in the 24-bit or 31-bit addressing mode, when equal compare values have been found, the contents of bit positions 32-63 of general registers 1 and 3 can be appropriate (depending on the contents of the tree) for the subsequent execution of COMPARE AND FORM CODEWORD. The contents of bit positions 32-63 of general register 2, shifted right 16 bit positions, can be similarly appropriate, and they can provide for minimal recomparison of partially equal keys. The same applies in the 64-bit addressing mode except to the contents of bit positions 0-63 of the registers and with the contents of bit positions 0-63 of general register 2 shifted right 48 bit positions. Refer to "Sorting Instructions" on page A-53 for a discussion of trees and their use in sorting.
3. The program should avoid placing a nonzero value in bit positions 32-38 of general register 5 when in the 24-bit addressing mode. If any bit in bit positions 32-38 is a one, the nodes of the tree will not be examined successively.
4. When bits 32-63 of general register 0 are negative in the 24-bit or 31-bit addressing mode, or when bits 0-63 are negative in the 64-bit mode, and provided that the tree has been updated

properly previously, the node represented by general registers 0 and 1 either is the node or is equal to the node (equal keys) that would be selected if the unit of operation continued. In this case, ending the unit of operation and setting condition code 3 is a faster means of selecting an appropriate node because it does not require further examination and updating of the tree.

5. Setting condition code 3 provides improved performance when the replacement record is equal to the old winner and, more importantly (since the first case can be detected by means of the condition code of CFC), when the update path contains a negative codeword, indicating equality with the old winner.
6. In those cases when the codeword in the node is less than or equal to the codeword in general register 0, depending on the model, the contents of the node may be fetched and subsequently stored back. As a result, any of the following may occur for the storage location containing the node: a PER storage-alteration event may be recognized; a protection exception for storing may be recognized; and, provided no access exceptions exist, the change bit may be set to one. Because the contents of storage remain unchanged, the change bit may or may not be one when a PER storage-alteration event is recognized.
7. Special precautions should be taken when UPDATE TREE is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.
8. Further programming notes concerning interruptible instructions are included in "Interruptible Instructions" on page 5-20.
9. The storage-operand references for UPDATE TREE may be multiple-access references. (See "Storage-Operand Consistency" on page 5-95.)
10. Figure 7-126 on page 7-244 is a summary of the operation of UPDATE TREE in the 24-bit or 31-bit addressing mode, and Figure 7-127 on page 7-245 is a summary of the operation in the 64-bit addressing mode.

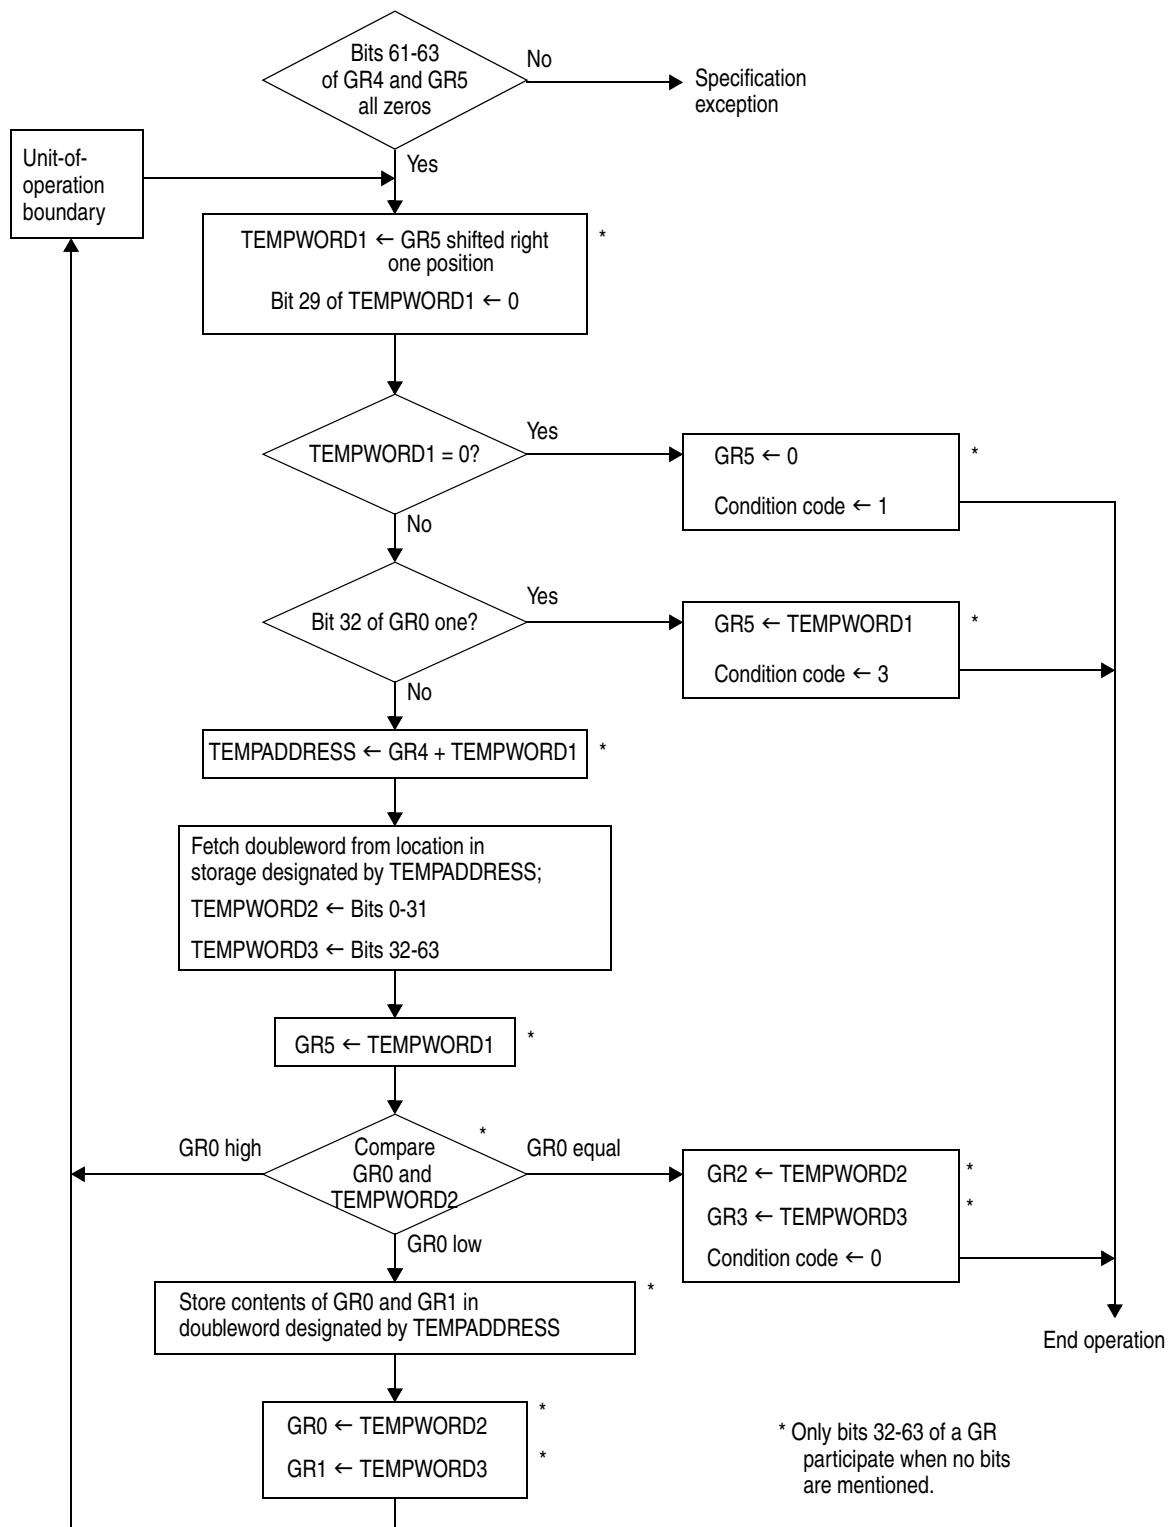

Figure 7-126. Execution of UPDATE TREE in the 24-Bit or 31-Bit Addressing Mode

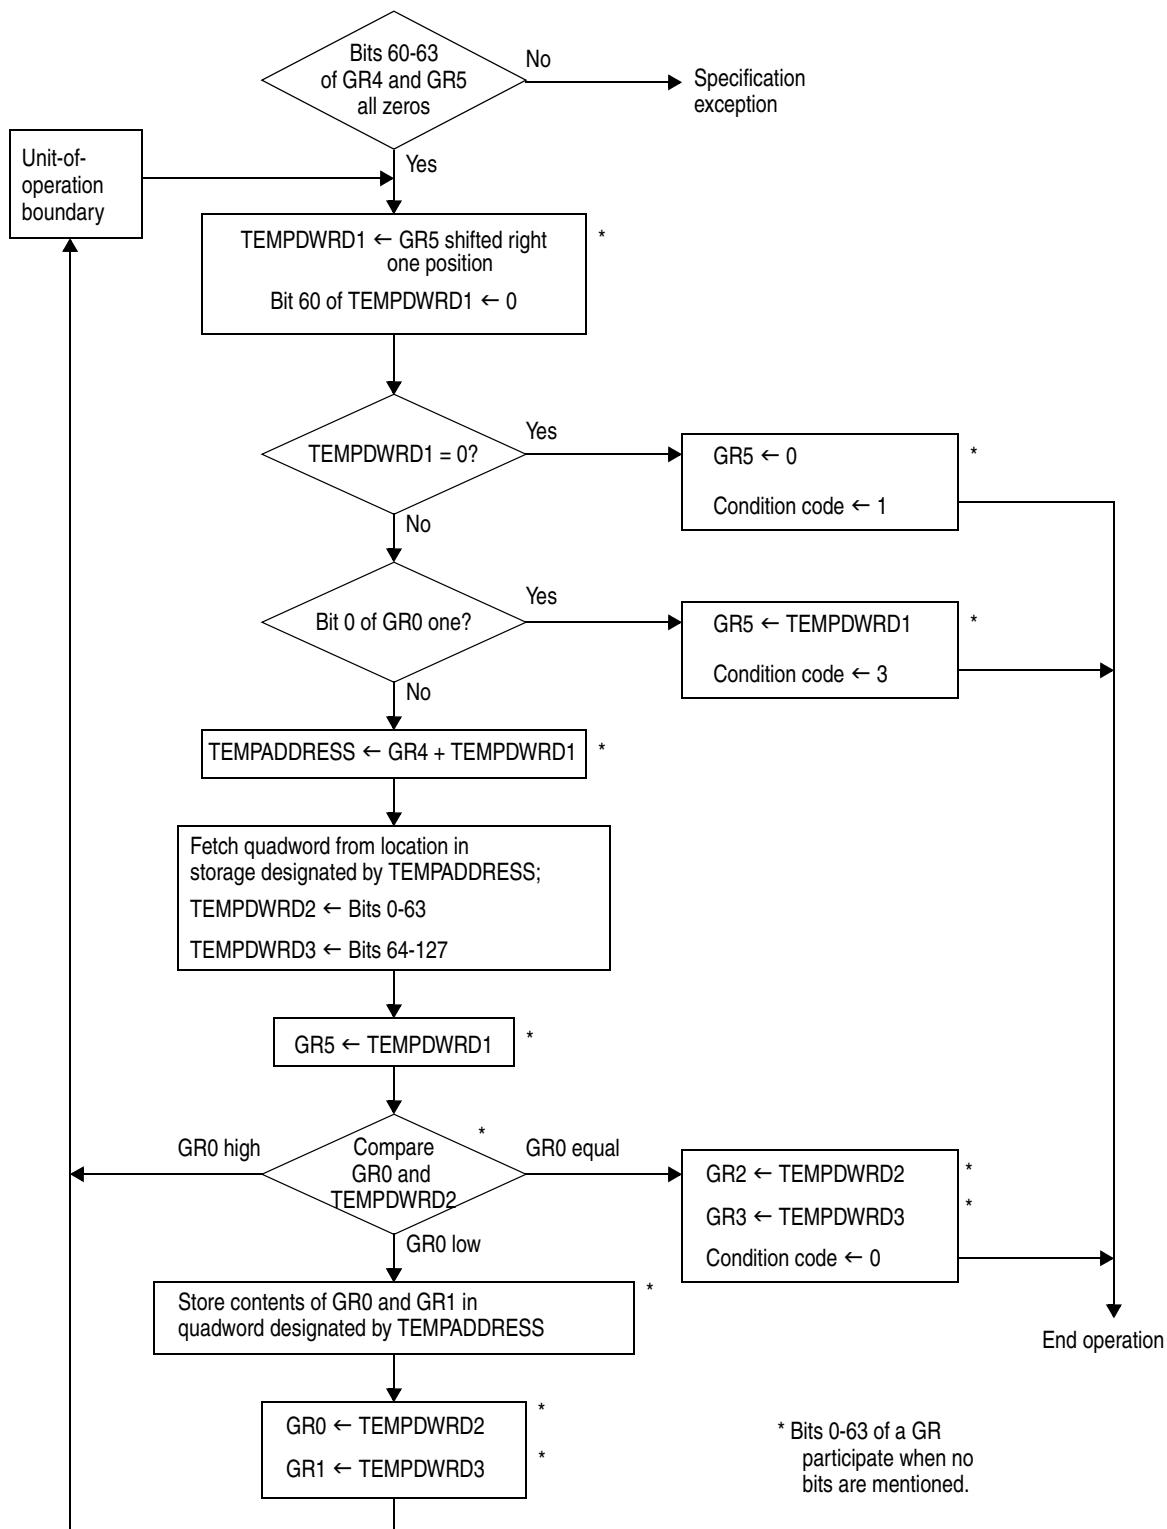

Figure 7-127. Execution of UPDATE TREE in the 64-Bit Addressing Mode

Other Instructions for Decimal Operands . . . . .	8-4	ZERO AND ADD . . . . .	8-13
Decimal-Operand Data Exception . . . . .	8-4		

The decimal instructions of this chapter perform arithmetic and editing operations on decimal data. Additional operations on decimal data are provided by several of the instructions in Chapter 7, "General Instructions." Also, several instructions in Chapter 20, "Decimal-Floating-Point Instructions" operate on decimal numbers in the packed-decimal format. Except for decimal-floating-point instructions, decimal operands always reside in storage, and most decimal instructions use the SS instruction format. Decimal operands occupy storage fields that can start on any byte boundary. For decimal-floating-point instructions, the packed-decimal operands are fixed length and occupy a general register, or general register pair.

## Decimal-Number Formats

Decimal numbers may be represented in several formats, including zoned, signed-packed-decimal and unsigned-packed-decimal. These formats are of variable length; most instructions used to operate on these formats specify the length of their operands and results. Each byte of a format consists of a pair of four-bit codes; the four-bit codes include decimal-digit codes, sign codes, and a zone code.

### Zoned Format

In the zoned format, the rightmost four bits of a byte are called the numeric bits (N) and normally consist

of a code representing a decimal digit. The leftmost four bits of a byte are called the zone bits (Z), except for the rightmost byte of a decimal operand, where these bits may be treated either as a zone or as a sign (S).

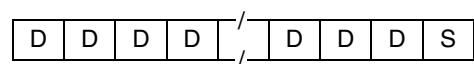

Decimal digits in the zoned format may be part of a larger character set, which includes also alphabetic and special characters. The zoned format is, therefore, suitable for input, editing, and output of numeric data in human-readable form. There are no decimal-arithmetic instructions which operate directly on decimal numbers in the zoned format; such numbers must first be converted to the signed-packed-decimal format.

The editing instructions produce a result of up to 256 bytes; each byte may be a decimal digit in the zoned format, a message byte, or a fill byte.

### Packed-Decimal Formats

There are two packed-decimal formats, signed-packed, and unsigned-packed.

#### Signed-Packed-Decimal Format

In the signed-packed-decimal format, each byte contains two decimal digits (D), except for the rightmost byte, which contains a sign (S) to the right of a decimal digit. Decimal arithmetic is performed with operands in the signed-packed-decimal format and

generates results in the signed-packed-decimal format.

The signed-packed-decimal operands and results of decimal-arithmetic instructions may be up to 16 bytes (31 digits and sign), except that the maximum length of a multiplier or divisor is eight bytes (15 digits and sign). In division, the sum of the lengths of the quotient and remainder may be from two to 16 bytes. The editing instructions can fetch as many as 256 decimal digits from one or more decimal numbers of variable length, each in the signed-packed-decimal format.

### Unsigned-Packed-Decimal Format

In the unsigned-packed-decimal format, each byte contains two decimal digits (D) and there is no sign. The unsigned-packed-decimal format can be used as the source operand of the editing instructions, as the second operand of MOVE WITH OFFSET, and is also used by the decimal floating-point (DFP) instructions CONVERT TO UNSIGNED PACKED and CONVERT FROM UNSIGNED PACKED.

### Decimal Codes

The decimal digits 0-9 have the binary encoding 0000-1001.

The preferred sign codes are 1100 for plus and 1101 for minus. These are the sign codes generated for the results of the decimal-arithmetic instructions and the CONVERT TO DECIMAL instruction. The instructions PACK ASCII and PACK UNICODE supply an implied positive sign (1100 binary). The DFP instructions CONVERT TO SIGNED PACKED include a plus sign-code selection bit. The plus sign can be encoded as either 1100 or 1111.

Alternate sign codes are also recognized as valid in the sign position: 1010, 1110, and 1111 are alternate codes for plus, and 1011 is an alternate code for minus. Alternate sign codes are accepted for any decimal source operand, but are not generated in the completed result of a decimal-arithmetic instruction or CONVERT TO DECIMAL. This is true even when an operand remains otherwise unchanged, such as when adding zero to a number. An alternate sign code is, however, left unchanged by MOVE NUMERICS, MOVE WITH OFFSET, MOVE ZONES, PACK, and UNPACK.

When an invalid sign or digit code is detected, a data exception is recognized. For the decimal-arithmetic instructions and CONVERT TO BINARY, and the decimal floating-point instructions CONVERT FROM SIGNED PACKED and CONVERT FROM UNSIGNED PACKED, the operation is suppressed.

For the editing instructions EDIT and EDIT AND MARK, an invalid sign code is not recognized. The operation is terminated for a data exception due to an invalid digit code. No validity checking is performed by MOVE NUMERICS, MOVE WITH OFFSET, MOVE ZONES, PACK, PACK ASCII, PACK UNICODE, and UNPACK. The instructions UNPACK ASCII and UNPACK UNICODE do not check for invalid digit codes; invalid sign codes are recognized, but are not reported as a data exception, instead condition code 3 is set.

The zone code 1111 is generated in the left four bit positions of each byte representing a zone and a decimal digit in zoned-format results. Zoned-format results are produced by EDIT, EDIT AND MARK, and UNPACK. For EDIT and EDIT AND MARK, each result byte representing a zoned-format decimal digit contains the zone code 1111 in the left four bit positions and the decimal-digit code in the right four bit positions. For UNPACK, zone bits with a coding of 1111 are supplied for all bytes except the rightmost byte, the zone of which receives the sign.

The meaning of the decimal codes is summarized in Figure 8-1.

Code (Binary)	Recognized As	
	Digit	Sign
0000	0	Invalid
0001	1	Invalid
0010	2	Invalid
0011	3	Invalid
0100	4	Invalid
0101	5	Invalid
0110	6	Invalid
0111	7	Invalid
1000	8	Invalid
1001	9	Invalid
1010	Invalid	Plus
1011	Invalid	Minus
1100	Invalid	Plus (preferred)
1101	Invalid	Minus (preferred)
1110	Invalid	Plus
1111	Invalid	Plus (zone)

Figure 8-1. Summary of Digit and Sign Codes

**Programming Note:** Since 1111 is both the zone code and an alternate code for plus, unsigned (positive) decimal numbers may be represented in the zoned format with 1111 zone codes in all byte positions. The result of the PACK instruction converting such a number to the signed-packed-decimal format may be used directly as an operand for decimal instructions.

## Decimal Operations

The decimal instructions in this chapter consist of two classes, the decimal-arithmetic instructions and the editing instructions.

### Decimal-Arithmetic Instructions

The decimal-arithmetic instructions perform addition, subtraction, multiplication, division, comparison, and shifting.

Operands of the decimal-arithmetic instructions are in the signed-packed-decimal format and are treated as signed decimal integers. A decimal integer is represented in true form as an absolute value with a separate plus or minus sign. It contains an odd number of decimal digits, from one to 31, and the sign;

this corresponds to an operand length of one to 16 bytes.

A decimal zero normally has a plus sign, but multiplication, division, and overflow may produce a zero value with a minus sign. Such a negative zero is a valid operand and is treated as equal to a positive zero by COMPARE DECIMAL.

The lengths of the two operands specified in the instruction need not be the same. If necessary, the shorter operand is considered to be extended with zeros on the left. Results, however, cannot exceed the first-operand length as specified in the instruction.

When a carry or leftmost nonzero digits of the result are lost because the first-operand field is too short, the result is obtained by ignoring the overflow digits, condition code 3 is set, and, if the decimal-overflow mask bit is one, a program interruption for decimal overflow occurs. The operand lengths alone are not an indication of overflow; nonzero digits must have been lost during the operation.

The operands of decimal-arithmetic instructions should not overlap at all or should have coincident rightmost bytes. In ZERO AND ADD, the operands may also overlap in such a manner that the rightmost byte of the first operand (which becomes the result) is to the right of the rightmost byte of the second operand. For these cases of proper overlap, the result is obtained as if operands were processed right to left. Because the codes for digits and signs are verified during the performance of the arithmetic, improperly overlapping operands are recognized as data exceptions. However, in ZERO AND ADD when the rightmost byte of the first operand is to the left of the rightmost byte of the second operand, the entire second operand may be fetched, depending on the model, before any storing occurs, which will cause a data exception not to be recognized. See “Interlocks within a Single Instruction” on page 5-87 for how overlap is detected in the access-register mode.

**Programming Note:** A signed-packed-decimal number in storage may be designated as both the first and second operand of ADD DECIMAL, COMPARE DECIMAL, DIVIDE DECIMAL, MULTIPLY DECIMAL, SUBTRACT DECIMAL, or ZERO AND ADD. Thus, a decimal number may be added to itself, compared with itself, and so forth; SUBTRACT DECIMAL may be used to set a decimal field in storage to zero; and, for MULTIPLY DECIMAL, a decimal number may be

squared in place. In these cases, the lengths of the two operands are not necessarily equal and may, depending on the instruction, be prohibited from being equal.

## Editing Instructions

The editing instructions are EDIT and EDIT AND MARK. For these instructions, only the first operand (the pattern) has an explicitly specified length. The second operand (the source) is considered to have as many digits as necessary for the completion of the operation.

Overlapping operands for the editing instructions yield unpredictable results.

## Execution of Decimal Instructions

During the execution of a decimal instruction, all bytes of the operands are not necessarily accessed concurrently, and the fetch and store accesses to a single location do not necessarily occur one immediately after the other. Furthermore, for decimal instructions, data in source fields may be accessed more than once, and intermediate values may be placed in the result field that may differ from the original operand and final result values. (See "Storage-Operand Consistency" on page 5-95.) Thus, in a multiprocessing configuration, an instruction such as ADD DECIMAL cannot be safely used to update a shared storage location when the possibility exists that another CPU may also be updating that location.

## Other Instructions for Decimal Operands

In addition to the decimal-arithmetic instructions in this chapter, (which operate on decimal numbers in the signed-packed-decimal format) several other instructions are provided for operating on decimal data in the zoned, signed-packed-decimal, or unsigned-packed-decimal format.

The editing instructions (described in this chapter) convert decimal numbers in either the signed-packed-decimal or unsigned-packed-decimal format to the zoned format. Zoned results of up to 256 bytes in length can be produced.

CONVERT TO DECIMAL and CONVERT TO BINARY (described in Chapter 7) provide conversion between signed-binary-integer formats and decimal numbers in the signed-packed-decimal format. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

CONVERT TO SIGNED PACKED and CONVERT FROM SIGNED PACKED (described in Chapter 20) provide conversion between decimal floating point (DFP) formats and the signed-packed-decimal format. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

CONVERT TO UNSIGNED PACKED and CONVERT FROM UNSIGNED PACKED (described in Chapter 20) provide conversion between decimal floating point (DFP) formats and the unsigned-packed-decimal format. Unsigned-packed-decimal operands of up to 16 bytes in length (32 digits) can be processed.

MOVE WITH OFFSET (described in Chapter 7) operates on data in the packed format. (The first operand is treated as signed-packed decimal and the second operand as unsigned-packed decimal.) Operands are not checked for valid codes. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

PACK, UNPACK, PACK ASCII, UNPACK ASCII, PACK UNICODE, and UNPACK UNICODE provide conversion between zoned or character data and signed-packed-decimal data. Operands are not checked for valid codes. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

MOVE NUMERICS and MOVE ZONES (described in Chapter 7) operate on data in the zoned format. Operands are not checked for valid codes. Zoned operands of up to 256 bytes in length can be processed.

## Decimal-Operand Data Exception

A decimal-operand data exception is recognized when any of the following is true:

1. The sign or digit codes are invalid in the operands of the decimal instructions or in CONVERT TO BINARY (described in Chapter 7, "General

Instructions"); or in CONVERT FROM SIGNED PACKED and CONVERT FROM UNSIGNED PACKED (described in Chapter 20, "Decimal Floating-Point Instructions").

2. The operand fields in ADD DECIMAL, COMPARE DECIMAL, DIVIDE DECIMAL, MULTIPLY DECIMAL, and SUBTRACT DECIMAL overlap in a way other than with coincident rightmost bytes; or operand fields in ZERO AND ADD overlap, and the rightmost byte of the second operand is to the right of the rightmost byte of the first operand. On some models, the improper overlap of operands for ZERO AND ADD is not recognized as a decimal-operand data exception; instead, the operation is performed as if the entire second operand were fetched before any byte of the result is stored.
3. The multiplicand in MULTIPLY DECIMAL has an insufficient number of leftmost zeros.

A decimal-operand data exception causes the operation to be suppressed, except that, for EDIT and EDIT AND MARK, and COMPRESSION CALL, the operation may be suppressed or terminated. In the

case of EDIT and EDIT AND MARK, and COMPRESSION CALL, an invalid sign code cannot occur.

## Instructions

The decimal instructions and their mnemonics, formats, and operation codes are listed in Figure 8-2 on page 8-5. The figure also indicates when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

**Note:** In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For ADD DECIMAL, for example, AP is the mnemonic and D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>) the operand designation.

**Programming Note:** The decimal instruction TEST DECIMAL is available when the extended-translation facility 2 is installed.

Name	Mne-monnic	Characteristics						Op Code	Page	
ADD DECIMAL	AP	SS	C	A	Dd	DF	ST	B <sub>1</sub> B <sub>2</sub>	FA	8-6
COMPARE DECIMAL	CP	SS	C	A	Dd		ST	B <sub>1</sub> B <sub>2</sub>	F9	8-6
DIVIDE DECIMAL	DP	SS		A SP	Dd	DK	ST	B <sub>1</sub> B <sub>2</sub>	FD	8-7
EDIT	ED	SS	C	A	Dd		ST	B <sub>1</sub> B <sub>2</sub>	DE	8-7
EDIT AND MARK	EDMK	SS	C	A	Dd	G1	ST	B <sub>1</sub> B <sub>2</sub>	DF	8-10
MULTIPLY DECIMAL	MP	SS		A SP	Dd		ST	B <sub>1</sub> B <sub>2</sub>	FC	8-11
SHIFT AND ROUND DECIMAL	SRP	SS	C	A	Dd	DF	ST	B <sub>1</sub> B <sub>2</sub>	F0	8-12
SUBTRACT DECIMAL	SP	SS	C	A	Dd	DF	ST	B <sub>1</sub> B <sub>2</sub>	FB	8-13
TEST DECIMAL	TP	RSL	C E2	A			ST	B <sub>1</sub> B <sub>2</sub>	EBC0	8-13
ZERO AND ADD	ZAP	SS	C	A	Dd	DF	ST	B <sub>1</sub> B <sub>2</sub>	F8	8-13

### Explanation:

- A Access exceptions for logical addresses.
- B<sub>1</sub> B<sub>1</sub> field designates an access register in the access-register mode.
- B<sub>2</sub> B<sub>2</sub> field designates an access register in the access-register mode.
- C Condition code is set.
- Dd Decimal-operand data exception.
- DF Decimal-overflow exception.
- DK Decimal-divide exception.
- E2 Extended-translation facility 2.
- G1 Instruction execution includes the implied use of general register 1.
- RSL RSL instruction format.
- SP Specification exception.
- SS SS instruction format.
- ST PER storage-alteration event.

Figure 8-2. Summary of Decimal Instructions

## ADD DECIMAL

AP	$D_1(L_1, B_1), D_2(L_2, B_2)$						[SS]
'FA'	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>	
0	8	12	16	20	32	36	47

The second operand is added to the first operand, and the resulting sum is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

Addition is algebraic, taking into account the signs and all digits of both operands. All sign and digit codes are checked for validity.

If the first operand is too short to contain all leftmost nonzero digits of the sum, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs.

The sign of the sum is determined by the rules of algebra. In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, a zero result is given either a positive or negative sign, as determined by what the sign of the correct sum would have been.

### ***Resulting Condition Code:***

- 0 Result zero; no overflow
- 1 Result less than zero; no overflow
- 2 Result greater than zero; no overflow
- 3 Overflow

### ***Program Exceptions:***

- Access (fetch, operand 2; fetch and store, operand 1)
- Data
- Decimal overflow

**Programming Note:** An example of the use of the ADD DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

## COMPARE DECIMAL

CP	$D_1(L_1, B_1), D_2(L_2, B_2)$						[SS]
'F9'	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>	
0	8	12	16	20	32	36	47

The first operand is compared with the second operand, and the result is indicated in the condition code. The operands are in the signed-packed-decimal format.

Comparison is algebraic and follows the procedure for decimal subtraction, except that both operands remain unchanged. When the difference is zero, the operands are equal. When a nonzero difference is positive or negative, the first operand is high or low, respectively.

Overflow cannot occur because the difference is discarded.

All sign and digit codes are checked for validity.

### ***Resulting Condition Code:***

- 0 Operands equal
- 1 First operand low
- 2 First operand high
- 3 --

### ***Program Exceptions:***

- Access (fetch, operand 2; fetch and store, operand 1)
- Data

### ***Programming Notes:***

- 1 An example of the use of the COMPARE DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
- 2 The preferred and alternate sign codes for a particular sign are treated as equivalent for comparison purposes.
- 3 A negative zero and a positive zero compare equal.

## DIVIDE DECIMAL

DP	$D_1(L_1, B_1), D_2(L_2, B_2)$						[SS]
'FD'	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>	
0	8	12	16	20	32	36	47

The first operand (the dividend) is divided by the second operand (the divisor). The resulting quotient and remainder are placed at the first-operand location. The operands and results are in the signed-packed-decimal format.

The quotient is placed leftmost in the first-operand location. The number of bytes in the quotient field is equal to the difference between the dividend and divisor lengths ( $L_1 - L_2$ ). The remainder is placed rightmost in the first-operand location and has a length equal to the divisor length. Together, the quotient and remainder fields occupy the entire first operand; therefore, the address of the quotient is the address of the first operand.

The divisor length cannot exceed 15 digits and sign ( $L_2$  not greater than seven) and must be less than the dividend length ( $L_2$  less than  $L_1$ ); otherwise, a specification exception is recognized.

The dividend, divisor, quotient, and remainder are each signed decimal integers in the signed-packed-decimal format and are right-aligned in their fields. All sign and digit codes of the dividend and divisor are checked for validity.

The sign of the quotient is determined by the rules of algebra from the dividend and divisor signs. The sign of the remainder has the same value as the dividend sign. These rules hold even when the quotient or remainder is zero.

Overflow cannot occur. If the divisor is zero or the quotient is too large to be represented by the number of digits specified, a decimal-divide exception is recognized. This includes the case of division of zero by zero. The decimal-divide exception is indicated only if the sign codes of both the dividend and divisor are valid, and only if the digit or digits used in establishing the exception are valid.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2; fetch and store, operand 1)
- Data
- Decimal divide
- Specification

## Programming Notes:

1. An example of the use of the DIVIDE DECIMAL instruction is given in Appendix A, "Number Representation and Instruction-Use Examples."
2. The dividend cannot exceed 31 digits and sign. Since the remainder cannot be shorter than one digit and sign, the quotient cannot exceed 29 digits and sign.
3. The condition for a decimal-divide exception can be determined by a trial comparison. The leftmost digit of the divisor is aligned one digit to the right of the leftmost dividend digit, with rightmost zeros appended up to the length of the dividend. When the divisor, so aligned, is less than or equal to the dividend, ignoring signs, a divide exception is indicated.
4. If a data exception does not exist, a decimal-divide exception occurs when the leftmost dividend digit is not zero.

## EDIT

ED	$D_1(L, B_1), D_2(B_2)$						[SS]
'DE'	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>		
0	8	16	20	32	36	47	

The second operand (the source), which normally contains one or more decimal numbers in the signed-packed-decimal or unsigned-packed-decimal format, is changed to the zoned format and modified under the control of the first operand (the pattern). The edited result replaces the first operand.

The length field specifies the length of the first operand, which may contain bytes of any value.

The length of the source is determined by the operation according to the contents of the pattern. The source normally consists of one or more decimal numbers, each in the signed-packed-decimal or unsigned-packed-decimal format. The leftmost four bits of each source byte must specify a decimal-digit code (0000-1001); a sign code (1010-1111) is recog-

nized as a data exception. The rightmost four bits may specify either a sign code or a decimal-digit code. Access and data exceptions are recognized only for those bytes in the second operand which are actually required.

The result is obtained as if both operands were processed left to right one byte at a time. Overlapping pattern and source fields give unpredictable results.

During the editing process, each byte of the pattern is affected in one of three ways:

1. It is left unchanged.
2. It is replaced by a source digit expanded to the zoned format.
3. It is replaced by the first byte in the pattern, called the fill byte.

Which of the three actions takes place is determined by one or more of the following: the type of the pattern byte, the state of the significance indicator, and whether the source digit examined is zero.

**Pattern Bytes:** There are four types of pattern bytes: digit selector, significance starter, field separator, and message byte. Their coding is as follows:

Name	Code (Binary)
Digit Selector	0010 0000
Significance starter	0010 0001
Field separator	0010 0010
Message byte	Any other

The detection of either a digit selector or a significance starter in the pattern causes an examination to be made of the significance indicator and of a source digit. As a result, either the expanded source digit or the fill byte, as appropriate, is selected to replace the pattern byte. Additionally, encountering a digit selector or a significance starter may cause the significance indicator to be changed.

The field separator identifies individual fields in a multiple-field editing operation. It is always replaced in the result by the fill byte, and the significance indicator is always off after the field separator is encountered.

Message bytes in the pattern are either replaced by the fill byte or remain unchanged in the result, depending on the state of the significance indicator.

They may thus be used for padding, punctuation, or text in the significant portion of a field or for the insertion of sign-dependent symbols.

**Fill Byte:** The first byte of the pattern is used as the fill byte. The fill byte can have any code and may concurrently specify a control function. If this byte is a digit selector or significance starter, the indicated editing action is taken after the code has been assigned to the fill byte.

**Source Digits:** Each time a digit selector or significance starter is encountered in the pattern, a new source digit is examined for placement in the pattern field. Either the source digit is disregarded, or it is expanded to the zoned format, by appending the zone code 1111 on the left, and stored in place of the pattern byte.

Execution is as if the source digits were selected one byte at a time and as if a source byte were fetched for inspection only once during an editing operation. Each source digit is examined only once for a zero value. The leftmost four bits of each byte are examined first, and the rightmost four bits, when they represent a decimal-digit code, remain available for the next pattern byte that calls for a digit examination. When the leftmost four bits contain an invalid digit code, a data exception is recognized, and the operation is terminated.

At the time the left digit of a source byte is examined, the rightmost four bits are checked for the existence of a sign code. When a sign code is encountered in the rightmost four bit positions, these bits are not treated as a decimal-digit code, and a new source byte is fetched from storage when the next pattern byte calls for a source-digit examination.

When the pattern contains no digit selector or significance starter, no source bytes are fetched and examined.

**Significance Indicator:** The significance indicator is turned on or off to indicate the significance or non-significance, respectively, of subsequent source digits or message bytes. Significant source digits replace their corresponding digit selectors or significance starters in the result. Significant message bytes remain unchanged in the result.

The significance indicator, by its on or off state, indicates also the negative or positive value, respec-

tively, of a completed source field and is used as one factor in the setting of the condition code.

The significance indicator is set to off at the start of the editing operation, after a field separator is encountered, or after a source byte is examined that has a plus code in the rightmost four bit positions.

The significance indicator is set to on when a significance starter is encountered whose source digit is a valid decimal digit, or when a digit selector is encountered whose source digit is a nonzero decimal digit, provided that in both instances the source byte does not have a plus code in the rightmost four bit positions.

In all other situations, the significance indicator is not changed. A minus sign code has no effect on the significance indicator.

**Result Bytes:** The result of an editing operation replaces and is equal in length to the pattern. It is composed of pattern bytes, fill bytes, and zoned source digits.

If the pattern byte is a message byte and the significance indicator is on, the message byte remains unchanged in the result. If the pattern byte is a field separator or if the significance indicator is off when a message byte is encountered in the pattern, the fill byte replaces the pattern byte in the result.

If the digit selector or significance starter is encountered in the pattern with the significance indicator off and the source digit zero, the source digit is considered nonsignificant, and the fill byte replaces the pattern byte. If the digit selector or significance starter is encountered with either the significance indicator on or with a nonzero decimal source digit, the source digit is considered significant, is changed to the zoned format, and replaces the pattern byte in the result.

**Condition Code:** The sign and magnitude of the last field edited are used to set the condition code. The term “last field” refers to those source digits, if any, in the second operand selected by digit selectors or significance starters after the last field separator; if the pattern contains no field separator, there is only one field, which is considered to be the last field. If no such source digits are selected, the last field is considered to be of zero length.

Condition code 0 is set when the last field edited is zero or of zero length.

Condition code 1 is set when the last field edited is nonzero and the significance indicator is on. (This indicates a result less than zero if the last source byte examined contained a sign code in the rightmost four bits.)

Condition code 2 is set when the last field edited is nonzero and the significance indicator is off. (This indicates a result greater than zero if the last source byte examined contained a sign code in the rightmost four bits.)

Figure 8-3 on page 8-10 summarizes the functions of the EDIT and EDIT AND MARK operations. The leftmost four columns list all the significant combinations of the four conditions that can be encountered in the execution of an editing operation. The rightmost two columns list the action taken for each case — the type of byte placed in the result field and the new setting of the significance indicator.

#### **Resulting Condition Code:**

- 0 Last field zero or zero length
- 1 Last field less than zero
- 2 Last field greater than zero
- 3 --

#### **Program Exceptions:**

- Access (fetch, operand 2; fetch and store, operand 1)
- Data

#### **Programming Notes:**

1. Examples of the use of the EDIT instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. Editing includes sign and punctuation control, and the suppression and protection of leading zeros by replacing them with blanks or asterisks. It also facilitates programmed blanking of all-zero fields. Several fields may be edited in one operation, and numeric information may be combined with text.
3. In most cases, the source is shorter than the pattern because each four-bit source digit produces an eight-bit byte in the result.

Conditions				Results	
Pattern Byte	Previous State of Significance Indicator	Source Digit	Right Four Source Bits Are Plus Code	Result Byte	State of Significance Indicator at End of Digit Examination
Digit selector	Off	0	*	Fill byte	Off
		1-9	No	Source digit#	On
		1-9	Yes	Source digit#	Off
		0-9	No	Source digit	On
	On	0-9	Yes	Source digit	Off
		0	No	Fill byte	On
		0	Yes	Fill byte	Off
		1-9	No	Source digit#	On
Significance starter	Off	1-9	Yes	Source digit#	Off
		0-9	No	Source digit	On
		0-9	Yes	Source digit	Off
		0	No	Fill byte	On
	On	0	Yes	Fill byte	Off
		1-9	No	Source digit#	On
		1-9	Yes	Source digit#	Off
		0-9	No	Source digit	On
Field separator	*	**	**	Fill byte	Off
	Off	**	**	Fill byte	Off
Message byte	Off	**	**	Message byte	On

**Explanation:**

- \* No effect on result byte or on new state of significance indicator.
- \*\* Not applicable because source is not examined.
- # For EDIT AND MARK only, the address of the rightmost such result byte is placed in general register 1.

Figure 8-3. Summary of Editing Functions

4. The total number of digit selectors and significance starters in the pattern always equals the number of source digits edited.
5. If the fill byte is a blank, if no significance starter exists in the pattern, and if the source digit examined for each digit selector is zero, the editing operation blanks the result field.
6. The resulting condition code indicates whether or not the last field is all zeros and, if nonzero, reflects the state of the significance indicator. The significance indicator reflects the sign of the source field only if the last source byte examined contains a sign code in the rightmost four bits. For multiple-field editing operations, the condition code reflects the sign and value only of the field following the last field separator.
7. Significant performance degradation is possible when, with DAT on, the second-operand address of an EDIT instruction designates a location that is closer to the left of a 4K-byte boundary than the length of the first operand of that instruction. This is because the machine may perform a trial execution of the instruction to determine if the second operand actually crosses the boundary.

The second operand of EDIT, while normally shorter than the first operand, can in the extreme case have the same length as the first.

## EDIT AND MARK

EDMK	D <sub>1</sub> (L,B <sub>1</sub> ),D <sub>2</sub> (B <sub>2</sub> )	[SS]
'DF'	L B <sub>1</sub> D <sub>1</sub> B <sub>2</sub> D <sub>2</sub>	0 8 16 20 32 36 47

The second operand (the source), which normally contains one or more decimal numbers in the signed-packed-decimal or unsigned-packed-decimal format, is changed to the zoned format and modified under the control of the first operand (the pattern). The address of the first significant result byte is inserted in general register 1. The edited result replaces the pattern.

EDIT AND MARK is identical to EDIT, except for the additional function of inserting the address of the result byte in general register 1 if the result byte is a zoned source digit and the significance indicator was off before the examination. If no result byte meets

the criteria, general register 1 remains unchanged; if more than one result byte meets the criteria, the address of the rightmost such result byte is inserted.

In the 24-bit addressing mode, the address replaces bits 40-63 of general register 1, and bits 0-39 of the register are not changed. In the 31-bit addressing mode, the address replaces bits 33-63 of general register 1, bit 32 of the register is set to zero, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, the address replaces bits 0-63 of general register 1.

The contents of access register 1 remain unchanged.

See Figure 8-3 on page 8-10 for a summary of the EDIT and EDIT AND MARK operations.

#### ***Resulting Condition Code:***

- 0 Last field zero or zero length
- 1 Last field less than zero
- 2 Last field greater than zero
- 3 --

#### ***Program Exceptions:***

- Access (fetch, operand 2; fetch and store, operand 1)
- Data

#### ***Programming Notes:***

1. Examples of the use of the EDIT AND MARK instruction are given Appendix A, "Number Representation and Instruction-Use Examples."
2. EDIT AND MARK facilitates the programming of floating currency-symbol insertion. Using appropriate source and pattern data, the address inserted in general register 1 is one greater than the address where a floating currency-sign would be inserted. BRANCH ON COUNT (BCTR, BCTGR), with zero in the R<sub>2</sub> field, may be used to reduce the inserted address by one.
3. No address is inserted in general register 1 when the significance indicator is turned on as a result of encountering a significance starter with the corresponding source digit zero. To ensure that general register 1 contains a proper address when this occurs, the address of the pattern byte that immediately follows the appropriate signifi-

cance starter could be placed in the register beforehand.

4. When multiple fields are edited with one execution of the EDIT AND MARK instruction, the address, if any, inserted in general register 1 applies to the rightmost field edited for which the criteria were met.
5. See also the programming note under EDIT regarding performance degradation due to a possible trial execution.

## **MULTIPLY DECIMAL**

MP	D <sub>1</sub> (L <sub>1</sub> ,B <sub>1</sub> ),D <sub>2</sub> (L <sub>2</sub> ,B <sub>2</sub> )				[SS]		
'FC'	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>		D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
0	8	12	16	20	32	36	47

The product of the first operand (the multiplicand) and the second operand (the multiplier) is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

The multiplier length cannot exceed 15 digits and sign (L<sub>2</sub> not greater than seven) and must be less than the multiplicand length (L<sub>2</sub> less than L<sub>1</sub>); otherwise, a specification exception is recognized.

The multiplicand must have at least as many bytes of leftmost zeros as the number of bytes in the multiplier; otherwise, a data exception is recognized. This restriction ensures that no product overflow occurs.

The multiplicand, multiplier, and product are each signed decimal integers in the signed-packed-decimal format and are right-aligned in their fields. All sign and digit codes of the multiplicand and multiplier are checked for validity. The sign of the product is determined by the rules of algebra from the multiplier and multiplicand signs, even if one or both operands are zeros.

***Condition Code:*** The code remains unchanged.

#### ***Program Exceptions:***

- Access (fetch, operand 2; fetch and store, operand 1)
- Data
- Specification

**Programming Notes:**

1. An example of the use of the MULTIPLY DECIMAL instruction is given Appendix A, "Number Representation and Instruction-Use Examples."
2. The product cannot exceed 31 digits and sign. The leftmost digit of the product is always zero.

**SHIFT AND ROUND DECIMAL**

SRP	D <sub>1</sub> (L <sub>1</sub> ,B <sub>1</sub> ),D <sub>2</sub> (B <sub>2</sub> ),I <sub>3</sub>							[SS]
'F0'	L <sub>1</sub>	I <sub>3</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>		
0	8	12	16	20	32	36	47	

The first operand is shifted in the direction and for the number of decimal-digit positions specified by the second-operand address, and, when shifting to the right is specified, the absolute value of the first operand is rounded by the rounding digit, I<sub>3</sub>. The first operand and the result are in the signed-packed-decimal format.

The first operand is considered to be in the signed-packed-decimal format. Only its digit portion is shifted; the sign position does not participate in the shifting. Zeros are supplied for the vacated digit positions. The result replaces the first operand. Nothing is stored outside of the specified first-operand location.

The second-operand address, specified by the B<sub>2</sub> and D<sub>2</sub> fields, is not used to address data; bits 58-63 of that address are the shift value, and the leftmost bits of the address are ignored.

The shift value is a six-bit signed binary integer, indicating the direction and the number of decimal-digit positions to be shifted. Positive shift values specify shifting to the left. Negative shift values, which are represented in two's complement notation, specify shifting to the right. The following are examples of the interpretation of shift values:

Shift Value (Binary)	Amount and Direction
011111	31 digits to the left
000001	One digit to the left
000000	No shift
111111	One digit to the right
100000	32 digits to the right

For a right shift, the I<sub>3</sub> field, bits 12-15 of the instruction, is used as a decimal rounding digit. The first operand, which is treated as positive by ignoring the sign, is rounded by decimally adding the rounding digit to the leftmost of the digits to be shifted out and by propagating the carry, if any, to the left. The result of this addition is then shifted right. Except for validity checking and the participation in rounding, the digits shifted out of the rightmost decimal-digit position are ignored and are lost.

If one or more nonzero digits are shifted out during a left shift, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs. Overflow cannot occur for a right shift, with or without rounding, or when no shifting is specified.

In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, the sign of the result is the same as the original sign but with the preferred sign code.

A data exception is recognized when the first operand does not have valid sign and digit codes or when the rounding digit is not a valid digit code. The validity of the first-operand codes is checked even when no shift is specified, and the validity of the rounding digit is checked even when no addition for rounding takes place.

**Resulting Condition Code:**

- 0 Result zero; no overflow
- 1 Result less than zero; no overflow
- 2 Result greater than zero; no overflow
- 3 Overflow

**Program Exceptions:**

- Access (fetch and store, operand 1)
- Data
- Decimal overflow

**Programming Notes:**

1. Examples of the use of the SHIFT AND ROUND DECIMAL instruction are given in Appendix A, "Number Representation and Instruction-Use Examples."

2. SHIFT AND ROUND DECIMAL can be used for shifting up to 31 digit positions left and up to 32 digit positions right. This is sufficient to clear all digits of any decimal number even with rounding.
3. For right shifts, the rounding digit 5 provides conventional rounding of the result. The rounding digit 0 specifies truncation without rounding.
4. When the  $B_2$  field is zero, the six-bit shift value is obtained directly from bits 42-47 of the instruction.

## SUBTRACT DECIMAL

SP	$D_1(L_1, B_1), D_2(L_2, B_2)$							[SS]
	'FB'	$L_1$	$L_2$	$B_1$	$D_1$	$B_2$	$D_2$	
0	8	12	16	20		32	36	47

The second operand is subtracted from the first operand, and the resulting difference is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

SUBTRACT DECIMAL is executed the same as ADD DECIMAL, except that the second operand is considered to have a sign opposite to the sign in storage. The second operand in storage remains unchanged.

### Resulting Condition Code:

- 0 Result zero; no overflow
- 1 Result less than zero; no overflow
- 2 Result greater than zero; no overflow
- 3 Overflow

### Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data
- Decimal overflow

## TEST DECIMAL

TP	$D_1(L_1, B_1)$							[RSL]
	'EB'	$L_1$		$B_1$	$D_1$		'C0'	
0	8	12	16	20		32	40	47

The first operand is tested for valid decimal digits and a valid sign code, and the result is indicated in the

condition code. The operand is in the signed-packed-decimal format.

### Resulting Condition Code:

- 0 All digit codes and the sign valid
- 1 Sign invalid
- 2 At least one digit code invalid
- 3 Sign invalid and at least one digit code invalid

### Program Exceptions:

- Access (fetch, operand 1)
- Operation (if the extended-translation facility 2 is not installed)

## ZERO AND ADD

ZAP	$D_1(L_1, B_1), D_2(L_2, B_2)$							[SS]
	'F8'	$L_1$	$L_2$	$B_1$	$D_1$	$B_2$	$D_2$	
0	8	12	16	20		32	36	47

The second operand is placed at the first-operand location. The operation is equivalent to an addition to zero. The operand and result are in the signed-packed-decimal format.

Only the second operand is checked for valid sign and digit codes. Extra zeros are supplied on the left for the shorter operand if needed.

If the first operand is too short to contain all leftmost nonzero digits of the second operand, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs.

In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, a zero result is given the sign of the second operand but with the preferred sign code.

The two operands may overlap, provided the rightmost byte of the first operand is coincident with or to the right of the rightmost byte of the second operand. In this case, the result is obtained as if the operands were processed right to left. When the operands overlap and the rightmost byte of the first operand is to the left of the rightmost byte of the second operand, then, depending on the model, either a data

exception is recognized or the result is obtained as if the entire second operand were fetched before any byte of the result is stored.

***Resulting Condition Code:***

- 0 Result zero; no overflow
- 1 Result less than zero; no overflow
- 2 Result greater than zero; no overflow
- 3 Overflow

***Program Exceptions:***

- Access (fetch, operand 2; store, operand 1)
- Data
- Decimal overflow

**Programming Note:** An example of the use of the ZERO AND ADD instruction is given in Appendix A, "Number Representation and Instruction-Use Examples."

Floating-point instructions are used to perform calculations on operands having a wide range of magnitude and to obtain results scaled to preserve precision.

Floating-point operands have formats based on three radices: 2, 10, or 16. These radix values lead to the terminology “binary,” “decimal,” and “hexadecimal” floating point (BFP, DFP, and HFP), respectively. The formats are also based on three operand lengths: short (32 bits), long (64 bits), and extended (128 bits). Short operands require less storage than long or extended operands. On the other hand, long and extended operands permit greater precision in computation.

### Sign Bit

All floating-point data have a sign bit. The sign bit is zero for plus and one for minus.

### Finite Floating-Point Numbers

A finite floating-point number has three components: a sign bit, an exponent, and a significand. The magnitude (an unsigned value) of the number is the product of the significand and the radix raised to the power of the exponent. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

The significand consists of a string of digits, where each digit is an integral value from zero to one less than the radix (2, 10, or 16). (Thus, a BFP digit is one bit, an HFP digit is four bits, and a DFP digit is a value from zero to nine.) The number of digit positions in the significand is called the precision of the floating-point number. The significand has an implied radix point, which, depending on the view, may be considered to be on the left, to the right of the leftmost digit, on the right, or elsewhere.

The exponent, a signed value, is represented as an unsigned binary value by adding a bias; the result, for BFP and DFP, is called the biased exponent; for HFP, it is called the characteristic. The value of the bias depends on the view. In the *fraction view*, the radix point is considered to be the left of the significand. In the *left-units view*, the radix point is considered to be to the right of the leftmost digit. In the *right-units view*, the radix point is considered to be on the right of the significand. By choosing the appropriate bias, any finite floating-point number can be considered in any of these views, or even in another view. For the first three of these views, the bias is called the *fraction-*

*view bias*, *left-units-view bias*, and *right-units-view bias*, respectively. Except where otherwise indicated, HFP is defined in terms of the fraction view, BFP terms of the left-units view, and DFP in terms of the right-units view.

For HFP, the significand is considered to be a fraction with the implied radix point on the left. In this view, the significand is referred to as the fraction. For BFP, the significand consists of an implicit unit digit to the left of an implied radix point and an explicit fraction field to the right. For DFP, the significand is considered to be an integer with the implied radix point on the right.

### Infinities

BFP and DFP data include an infinite numeric datum, called infinity. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. An infinity has a sign bit. In comparisons, infinities of the same sign compare equal,  $+\infty$  compares greater than any finite number, and  $-\infty$  compares less than any finite number.

### Not-A-Number (NaN)

BFP and DFP data types include a nonnumeric datum, called not-a-number (or NaN). A NaN is produced in place of a numeric result after an invalid operation when there is no IEEE trap action. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area. A NaN has a sign bit, a NaN-type bit, and a payload.

### Signaling and Quiet NaNs

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from the corresponding quiet NaN (QNaN) by the NaN-type bit.

For BFP, the NaN-type bit is the leftmost bit of the fraction field, and is called the QNaN bit: a BFP NaN is an SNaN, or a QNaN, depending on whether the QNaN bit is zero, or one, respectively. For DFP, the NaN-type bit is in bit position 6 in all three formats, and is called the SNaN bit: a DFP NaN is a QNaN, or an SNaN, depending on whether the SNaN bit is zero, or one, respectively.

### Payload

Nans include diagnostic information called the payload. For BFP, the payload has two fewer bits than

the precision and is considered to be a left-aligned bit-reversed binary integer. For DFP, the payload has one fewer digit than the precision and is considered to be a right-aligned decimal integer.

For both BFP and DFP the payload of a NaN is considered to be an unsigned integer. Let  $p$  represent the precision, in digits, of a particular format. For DFP, bit 6 of the format is called the SNaN bit and the  $p-1$  digits in the trailing significand field are the numeric value of the payload. For BFP, the leftmost bit in the fraction field is called the QNaN bit and the remaining  $p-2$  bits of the fraction field are the numeric value of the payload.

The numeric value of the BFP NaN payload is bit-reversed. That is, the first bit to the right of the QNaN bit is considered to have a value of one, the next bit a value of two, and so on, with each bit having a value of twice the value of the bit to its left.

### Propagation of NaNs

Normally, QNaNs are just propagated during computations so that they will remain visible at the end; while an SNaN operand causes an IEEE-invalid-operation exception. If the IEEE-invalid-operation mask (FPC 0.0) is zero, the result is the corresponding QNaN, which is produced by inverting the NaN-type bit, and setting the IEEE-invalid-operation flag (FPC 1.0) is set to one. If the IEEE-invalid-operation mask (FPC 0.0) is one, the operation is suppressed, and a data exception for IEEE-invalid operation occurs.

### Default QNaN

A special QNaN is supplied as the default result for an IEEE-invalid-operation exception; it has a plus sign and a payload of zeros.

### Programming Notes:

1. The program can generate and assign values to the payload of a NaN. The CPU propagates those values unchanged, except that an SNaN is changed to the corresponding QNaN if the IEEE-invalid-operation mask bit is zero, and conversion to a narrower format truncates digits from the payload. For BFP, bits are truncated on the right; for DFP, digits are truncated on the left. For the PFPO-convert-floating-point-radix operation, payloads are preserved, except that payloads larger than the capacity of the target format are replaced by the default QNaN (payload zero).

2. Depending on the application, the program may or may not desire that an SNaN signal the IEEE invalid-operation exception. The sign-handling instructions LOAD COMPLEMENT, LOAD NEGATIVE, and LOAD POSITIVE do not signal the invalid-operation exception but, instead, treat SNaNs like any other data. LOAD AND TEST signals the invalid-operation exception when the operand is an SNaN. This instruction, in conjunction with the above instructions, gives the program the choice of either option.
3. The instructions LOAD LENGTHENED and LOAD ROUNDED change the precision of a floating-point datum. The BFP versions of these instructions signal the invalid-operation exception when the operand is an SNaN. The DFP instructions have a modifier bit to control whether the exception is signaled.

## Hexadecimal-Floating-Point (HFP)

Hexadecimal-floating-point (HFP) operands have formats which provide for exponents that specify powers of the radix 16 and significands that are hexadecimal numbers. The exponent range is the same for the short, long, and extended formats. The results of most operations on HFP data are truncated to fit into the target format, but there are instructions available to round the result when converting to a narrower format. For HFP operands, the implicit unit digit of the significand is always zero. Since the value of the significand and fraction are the same, HFP operations are described in terms of the fraction, and the term significand is not used.

Either normalized or unnormalized numbers may be used as operands for any HFP or DFP operation, where, for HFP, a normalized number is one having a nonzero leftmost fraction digit, or, for DFP, a normalized number is one having a nonzero leftmost significand digit. Most HFP instructions generate normalized results for greatest precision. HFP add and subtract instructions that generate unnormalized results are also available.

## Binary Floating-Point (BFP)

Binary-floating-point (BFP) operands have formats which provide for exponents that specify powers of the radix 2 and significands that are binary numbers. The exponent range differs for different formats, the

range being greater for the longer formats. In the long and extended formats, the exponent range is significantly greater for BFP data than for HFP data. The results of operations performed on BFP data are rounded automatically to fit into the target format; the manner of rounding is determined by a program-settable BFP rounding mode.

There are no unnormalized operands for BFP operations. For normal BFP numbers, the implicit unit digit of the significand is one. For values too small in magnitude to be represented in normalized form, the implicit unit digit is zero. These numbers are called “subnormal” numbers.<sup>1</sup> Unlike the HFP and DFP formats, where the same value can have multiple representations in a given format because of the possibility of unnormalized numbers, the BFP format does not allow such redundancy.

## Decimal Floating-Point (DFP)

Decimal-floating-point (DFP) operands have formats which provide for exponents that specify powers of the radix 10 and significands that are decimal numbers. The exponent range differs for different formats, the range being greater for the longer formats. The exponent range is greater for DFP data than for BFP data. The results of operations performed on DFP data are rounded automatically to fit into the target format; the manner of rounding is determined by a program-settable DFP rounding mode.

Like HFP, DFP numbers can be normalized or unnormalized. Either normalized or unnormalized numbers may be used as operands for any DFP operation. For DFP, a normalized number is one having a nonzero leftmost significand digit. Because of the possibility of unnormalized numbers, the same value can have multiple representations in a given DFP format. The representations having the same value are called members of a cohort. Unlike HFP, DFP instructions generate normalized results for greater precision only when the result is inexact. When the result is exact, most DFP instructions produce a value in the form that preserves information called the quantum.

### Canonical DFP Data

A *canonical DFP number* has only canonical declets, that is, the digits in the trailing-significand field are encoded using only the preferred DPD codes.

A *canonical DFP infinity* has bit 6 and all bits to the right of this in the format set to zeros.

A *canonical DFP NaN* has zeros in all bits to the right of the NaN-type bit in the combination field and only canonical declets in the trailing significand field.

Noncanonical DFP numbers, infinities, and NaNs are accepted as source operands, but all DFP results are canonical.

## Comparison of Floating-Point Number Representations

### Floating-Point Number Ranges

Figure 9-1 shows the range of numbers, in decimal form, that can be represented in different floating-point formats.

	Type	Short	Long	Extended
Nmax	BFP	$\pm 3.4 \times 10^{38}$	$\pm 1.8 \times 10^{308}$	$\pm 1.2 \times 10^{4932}$
	HFP	$\pm 7.2 \times 10^{75}$	$\pm 7.2 \times 10^{75}$	$\pm 7.2 \times 10^{75}$
	DFP	$\pm 1.0 \times 10^{91}$	$\pm 1.0 \times 10^{370}$	$\pm 1.0 \times 10^{6112}$
Nmin	BFP	$\pm 1.2 \times 10^{-38}$	$\pm 2.2 \times 10^{-308}$	$\pm 3.4 \times 10^{-4932}$
	HFP	$\pm 5.4 \times 10^{-79}$	$\pm 5.4 \times 10^{-79}$	$\pm 5.4 \times 10^{-79}$
	DFP	$\pm 1.0 \times 10^{-95}$	$\pm 1.0 \times 10^{-383}$	$\pm 1.0 \times 10^{-6143}$
Dmin	BFP	$\pm 1.4 \times 10^{-45}$	$\pm 4.9 \times 10^{-324}$	$\pm 6.5 \times 10^{-4966}$
	HFP	$\pm 5.1 \times 10^{-85}$	$\pm 1.2 \times 10^{-94}$	$\pm 1.7 \times 10^{-111}$
	DFP	$\pm 1.0 \times 10^{-101}$	$\pm 1.0 \times 10^{-398}$	$\pm 1.0 \times 10^{-6176}$

**Explanation:**

Dmin      Smallest (in magnitude) representable subnormal (BFP or DFP) or nonzero unnormalized (HFP) number.  
 Nmax      Largest (in magnitude) representable number.  
 Nmin      Smallest (in magnitude) representable normal (BFP or DFP) or normalized (HFP) number.

Values are decimal approximations.

Figure 9-1. Number Ranges for BFP and HFP Formats

### Equivalent Floating-Point Number Representations

The exponent of an HFP number is represented in the format as an unsigned seven-bit binary integer called the characteristic. The characteristic is obtained by adding 64 to the exponent value (excess-64 notation). The range of the characteristic is 0 to 127, which corresponds to an exponent range of -64 to +63.

1. Subnormal numbers were previously called “denormalized” numbers.

The exponent of a BFP or DFP datum is represented in the format as an unsigned binary integer called the biased exponent. The biased exponent is obtained by adding a bias to the exponent value. The number of bit positions containing the biased exponent, the value of the bias, and the exponent range depend on the data format (short, long, or extended) and are shown for the three formats in Figure 19-4 on page 19-3 and the three DFP formats in Figure 20-3 on page 20-6. Biased exponents are similar to the characteristics of the HFP format, except that, for BFP, special meanings are attached to biased exponents of all zeros and all ones. This is discussed in the section “Classes of BFP Data” on page 19-4.

In each of the three BFP or HFP formats, the binary or hexadecimal point of a number, respectively, is considered to be to the left of the leftmost fraction

digit. To the left of the point there is an implied unit digit, which is considered to be zero for HFP numbers or, for BFP numbers, one for normal numbers and zero for zeros and subnormal numbers.

Figure 9-2 on page 9-6 and Figure 9-3 on page 9-7 give examples of the closest representation of the same numbers in the BFP, DFP, and HFP formats, with BFP and DFP values being rounded to nearest and HFP values being truncated.

The figures do not necessarily show the results of conversions exactly. Rounding errors may make a small difference. Also, Figure 9-2 on page 9-6 shows corresponding rounded short-format numbers, not the long HFP results of conversion from short BFP operands.

Value	S	BE or C	Trailing Significand

Figure 9-3. Examples of Floating-Point Numbers in Long Format

#### Effective Width

The resolution of a floating-point format may be described in terms of the spacing between adjacent representable numbers in the format. This is called an ulp (unit in the last place). Thus, for example, when rounding to nearest, the maximum error is 1/2 ulp. The magnitude of an ulp is directly related to the precision of the format. Another way to measure the resolution of the format in the vicinity of a particular

value is in terms of relative spacing, which is simply the value of an ulp divided by the value of the number. Relative spacing may be converted to a form called effective width, which is very similar to precision. The *effective width* ( $W_x$ ) for any particular normalized floating-point value,  $v$ , is defined as:

$$W_x(v) = \log_x(v/u)$$

Where:

- u Value of a unit in the last position (ulp).
- v Value of the number.
- $W_x$  Effective width represented in base x.
- x Any arbitrary base.

When effective width is measured using the native base for a particular format, it differs from the precision (p) of the format as shown in the following relation:

$$p-1 \leq W_b \leq p$$

Where:

- b Native base of a particular format.
- p Precision of the format.
- $W_b$  Effective width for any normalized value represented in the native base b of the format.

The following figure shows the maximum and minimum values of the effective width for normalized numbers for all supported floating-point formats.

Length	Radix	$W_2$		$W_{10}$	
		Max	Min	Max	Min
Short	HFP	24.00	20.00	7.22	6.02
	BFP	24.00	23.00	7.22	6.92
	DFP	23.25	19.93	7.00	6.00
Long	HFP	56.00	52.00	16.86	15.65
	BFP	53.00	52.00	15.95	15.65
	DFP	53.15	49.83	16.00	15.00
Extended	HFP	112.00	108.00	33.72	32.51
	BFP	113.00	112.00	34.02	33.72
	DFP	112.95	109.62	34.00	33.00

**Explanation:**

$W_2$  effective width represented in base 2.  
 $W_{10}$  effective width represented in base 10.

Figure 9-4. Maximum and Minimum Effective Width

**Programming Note:** The following example using a 3-digit decimal significand, may be helpful in understanding the concept of effective width and the maximum and minimum values. Consider the three adjacent representable numbers, Va, Vb, and Vc, as shown in the following figure:

Symbol or Formula	Value
Va	9.99
Vb	10.0
Vc	10.1
Vb-Va	0.01
Vc-Vb	0.1

The distance between points Va and Vb (Vb-Va) represents a resolution of one part in a thousand; whereas, the distance between points Vb and Vc (Vc-Vb) represents a resolution of one part in a hundred. In the first case, the effective width is three digits; in the second case, it is only two digits. For other values in the format, the effective width lies between these two extremes.

## Floating-Point Data in Storage

All floating-point data formats appear in storage in the same left-to-right sequence as all other data formats. Bits of a data format that are numbered 0-7 constitute the byte in the leftmost (lowest-numbered) byte location in storage, bits 8-15 form the byte in the next sequential location, and so on. (See also the section “Storage Addressing” on page 3-2.)

Most of the floating-point instructions are defined in detail in this publication in Chapter 18, “Hexadecimal-Floating-Point Instructions,” Chapter 19, “Binary-Floating-Point Instructions,” and Chapter 20, “Decimal-Floating-Point Instructions.” This chapter, Chapter 9, defines in detail instructions called floating-point-support (FPS) instructions. The FPS instructions either have operands that may be in any floating-point format or have the function of converting between formats. This chapter also provides summary information about all of the floating-point instructions.

---

## Registers And Controls

### Floating-Point Registers

All floating-point instructions (FPS, BFP, DFP, and HFP) use the same 16 floating-point registers. The floating-point registers are identified by the numbers 0-15 and are designated by a four-bit R field in float-

ing-point instructions. Each floating-point register is 64 bits long and can contain either a short (32-bit) or a long (64-bit) floating-point operand.

A short floating-point datum requires only the left-most 32 bit positions of a floating-point register. The rightmost 32 bit positions of the register are ignored when the register is the source of an operand in the short format, and they remain unchanged when a short result is placed in the register.

A datum in the extended (128-bit) format occupies a register pair. Register pairs are formed by coupling the 16 registers as follows: 0 and 2, 4 and 6, 8 and 10, 12 and 14, 1 and 3, 5 and 7, 9 and 11, and 13 and 15.

Each of the eight pairs is referred to by the number of the lower-numbered register of the pair.

## Additional Floating-Point (AFP) Registers

Floating-point registers 0, 2, 4, and 6 are ones that were originally available on ESA/390 models. The remaining 12 floating-point registers (1, 3, 5, and 7-15) were added to ESA/390 and are referred to as the additional floating-point (AFP) registers. The AFP registers can be used only if bit 45 of control register 0, the AFP-register-control bit, is one. Attempting to use an AFP register when the AFP-register-control bit is zero results in an AFP-register data exception (DXC 1).

## Valid Floating-Point-Register Designations

Any installed register may be designated by an instruction to specify the register location of a short or long floating-point operand.

An instruction specifying a floating-point operand in the extended format must designate register 0, 1, 4, 5, 8, 9, 12, or 13; otherwise, a specification exception is recognized.

## Floating-Point-Control (FPC) Register

The floating-point-control (FPC) register is a 32-bit register that contains mask bits, flag bits, a data-exception code, and two rounding-mode fields. An overview of the FPC register is shown in Figure 9-5.

Details are shown in Figure 9-6 and in Figure 9-8. (In Figure 9-6, the abbreviations “IM” and “SF” are based on the terms “interruption mask” and “status flag,” respectively.)

The bits of the FPC register are often referred to as, for example, FPC 1.0, meaning bit 0 of byte 1 of the register.

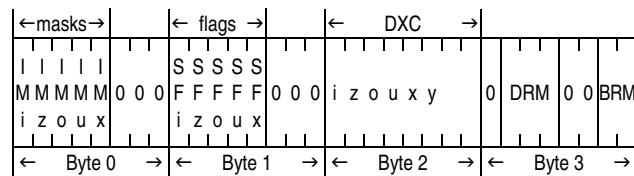

Figure 9-5. FPC Register Overview

Byte	Bit(s)	Name	Abbr.
0	0	IEEE-invalid-operation mask	IMi
0	1	IEEE-division-by-zero mask	IMz
0	2	IEEE-overflow mask	IMo
0	3	IEEE-underflow mask	IMu
0	4	IEEE-inexact mask	IMx
0	5-7	(Unassigned)	0
1	0	IEEE-invalid-operation flag	SFi
1	1	IEEE-division-by-zero flag	SFz
1	2	IEEE-overflow flag	SFo
1	3	IEEE-underflow flag	SFu

### IEEE Masks and Flags

The FPC register contains five IEEE mask bits and five IEEE flag bits that each correspond to one of the five IEEE exceptions that may be recognized when an IEEE computational instruction is executed. The masks bits, when one, cause an interruption to occur if an exception is recognized. If the mask bit for an exception is zero, the recognition of the exception causes the corresponding flag bit to be set to one. Thus, a flag bit indicates whether the corresponding exception has been recognized at least once since the program last set the flag bit to zero. Except for PFPO, the mask bits are ignored, and the flag bits remain unchanged, when exceptions are recognized for floating-point-support (FPS) and HFP instructions.

The IEEE flag bits in the FPC register are set to zero only by explicit program action, initial CPU reset, clear reset, or power-on reset.

### FPC DXC Byte

Byte 2 of the FPC register contains the data-exception code (DXC), which is an eight-bit code indicating the specific cause of a data exception. When the AFP-register-control bit, bit 45 of control register 0, is one and a program interruption causes the DXC to be placed at real location 147, the DXC is also placed in the DXC field of the FPC register. The DXC field in the FPC register remains unchanged when the AFP-register-control bit is zero or when any other program exception is reported. The DXC is described in “Data-Exception Code (DXC)” on page 6-14.

The DXC is a code, meaning it should be treated as an integer rather than as individual bits. However, when bits 6 and 7 are zero, bits 0-5 are bit significant; bits 0-4 (i,z,o,u,x) are trap flags and correspond to the same bits in bytes 0 and 1 of the FPC register (IEEE masks and IEEE flags), and bit 5 (y) is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude. The trap flag for an exception, instead of the IEEE flag, is set

to one when an interruption for the exception is enabled by the corresponding IEEE mask bit.

### Operations on the FPC Register

The following unprivileged instructions allow problem-state programs to operate on the FPC register:

```

EXTRACT FPC (DXC 2)
LOAD FPC (DXC 2)
LOAD FPC AND SIGNAL (DXC 3)
SET BFP ROUNDING MODE (DXC 2)
SET DFP ROUNDING MODE (DXC 3)
SET FPC (DXC 2)
SET FPC AND SIGNAL (DXC 3)
STORE FPC (DXC 2)

```

These instructions are subject to the AFP-register-control bit, bit 45 of control register 0. An attempt to execute any of the above instructions when the AFP-register-control bit is zero results in a data exception. The term (DXC 2) or (DXC 3) after the name indicates the type of exception: that is, BFP-instruction data exception, (DXC 2), or DFP-instruction data exception, (DXC 3), respectively.

**Programming Note:** The use of DXC 2 and DXC 3 for these floating-point-support (FPS) instructions is rather arbitrary, but assuming a valid operating system, these exceptions are never reported to the user, as the operating system will set bit 45 of control register 0 to one and re-issue the instruction.

### AFP-Register-Control Bit

Bit 45 of control register 0 is the AFP-register-control bit. The AFP registers, the BFP instructions, the DFP instructions, and PFPO can be used successfully only when the AFP-register-control bit is one. Attempting to use one of the 12 additional floating-point registers or executing PFPO when the AFP-register-control bit is zero results in an AFP-register data exception (DXC 1). Attempting to execute any BFP instruction when the AFP-register-control bit is zero results in a BFP-instruction data exception (DXC 2). Attempting to execute any DFP instruction when the AFP-register-control bit is zero results in a DFP-instruction data exception (DXC 3).

DXC 2 and 3 are mutually exclusive and are of higher priority than any other DXC. Thus, for example, DXC 2 (BFP instruction) takes precedence over any IEEE exception; and DXC 3 (DFP instruction) takes precedence over any IEEE exception. As another example,

if the conditions for both DXC 3 (DFP instruction) and DXC 1 (AFP register) exist, DXC 3 is reported.

If the conditions for both a data exception and a specification exception exist, it is unpredictable which exception is reported.

The initial value of the AFP-register-control bit is zero.

## IEEE Computational Operations

Instructions which operate on BFP or DFP source operands or produce BFP or DFP results and recognize IEEE exceptions are called IEEE computational operations, and the associated operands and results are sometimes referred to as IEEE operands and IEEE results, respectively.

Execution of IEEE computational operations normally follows a certain pattern. Source operands are first tested for special cases and then processed to form a result. The priority for testing of special cases is SNaN, QNaN, infinity, and then finite number.

If a source operand is an SNaN, an IEEE-invalid-operation exception is recognized; and, in the non-trap case, the result is set to the corresponding QNaN.

In the absence of a source SNaN, if a source operand is a QNaN the result is set to that QNaN.

Handling of the case when more than one source operand is a NaN is covered in the individual instruction descriptions.

In the absence of a NaN, if an operand is an infinity, special “infinity arithmetic” rules are followed to produce the result.

## Intermediate Values

In the normal case (when all source operands are finite numbers), first, a *precise intermediate value* is produced, then a *rounded intermediate value*. In the absence of trapped overflow and trapped underflow, the rounded intermediate value is used as the *delivered value*. For trapped overflow and trapped underflow, the rounded intermediate value is divided by a

*scale factor* to produce a *scaled value*, which is used as the delivered value. Finally, the delivered value is placed in the target location. For DFP, since the cohort for the delivered value may have multiple members, one member from the cohort must be selected. Selection is performed by choosing the member having a quantum closest to the *preferred quantum* (or for trapped overflow and trapped underflow, a *scaled preferred quantum*).

### Precise Intermediate Value

Every IEEE computational operation producing a numeric result computes a value called the *precise intermediate value*. This is the value that would have been computed were both the precision and exponent range unbounded.

### Precision-Rounded Value

Except when otherwise specified, the precise intermediate value is rounded to the precision of the target format, but with unbounded exponent range. This process is called *target-precision-constrained rounding*, and the value selected by this type of rounding is called the *precision-rounded value*.

### Denormalized Value

For IEEE targets, when the IEEE-underflow trap is disabled and the tininess condition exists, the precise intermediate value is rounded to fit in the destination format. That is, with both precision and exponent range of the target format. This process is called *denormalization rounding* and the value selected by this type of rounding is called the *denormalized value*.

### Functionally-Rounded Value

The instructions CONVERT TO FIXED, LOAD FP INTEGER, QUANTIZE, and REROUND, as an integral part of the function, take a source operand and modify it to fit in a subset of the destination format. This process is called *functionally-constrained rounding* and the value selected by this type of rounding is called the *functionally-rounded value*.

### Rounded Intermediate Value

In any particular instance, only one of the three rounding processes is performed and the value selected (precision-rounded value, denormalized value, or functionally-rounded value) is generically referred to as the *rounded intermediate value*.

## Scaled Value

For both overflow and underflow when the associated trap is enabled, the precision-rounded value is scaled to bring it into the representable exponent range of the target. This is called the *scaled value* and is derived as explained in the next section.

## Scale Factor ( $\Psi$ )

IEEE-overflow trap action and IEEE-underflow trap action produce a *scaled value* using a *scale factor*. The scaled value ( $z$ ) is computed from the precision-rounded value ( $g$ ) using the scale factor ( $\Psi$ ) as follows:

$$z = g \div \Psi$$

## Unsigned Scaling Exponent ( $\alpha$ )

For BFP and DFP instructions, the scale factor ( $\Psi$ ) is computed using the unsigned scaling exponent ( $\alpha$ ) and different formulas are used for overflow and underflow.

For overflow:

$$\Psi = b^{+\alpha}$$

For underflow:

$$\Psi = b^{-\alpha}$$

where  $b$  is the radix of the target (2 for BFP and 10 for DFP). The unsigned scaling exponent ( $\alpha$ ) depends on the type of operation and operand format.

For all BFP operations except LOAD ROUNDED,  $\alpha$  depends on the target format and is 192 for short, 1536 for long, and 24576 for extended. For BFP LOAD ROUNDED,  $\alpha$  depends on the source format, and is 512 for long and 8192 for extended.

For all DFP operations except LOAD ROUNDED,  $\alpha$  depends on the target format and is 576 for long and 9216 for extended. For DFP LOAD ROUNDED,  $\alpha$  depends on the source format, and is 192 for long and 3072 for extended.

## Signed Scaling Exponent ( $\Omega$ )

For PFPO convert floating-point radix, the scale factor ( $\Psi$ ) is computed using the signed scaling exponent ( $\Omega$ ) and the formula for the scale factor ( $\Psi$ ) is the same for overflow and underflow:

$$\Psi = b^{\Omega}$$

Where  $b$  is the radix (2, 10, and 16) for BFP, DFP and HFP, respectively. Thus, for overflow, the signed scaling exponent ( $\Omega$ ) is a positive value, and for underflow it is a negative value.

## IEEE Rounding

Rounding takes an input value, and, using the effective rounding method, selects a value from a permissible set. The input value, considered to be infinitely-precise, may be an operand of an instruction or the numeric output from an arithmetic operation. The effective rounding method may be the current rounding method specified in the BFP-rounding-mode or DFP-rounding-mode field of the FPC register; or, for some instructions, an explicit rounding method is specified by a modifier field. For the PFPO-convert-floating-point-radix operation, rounding is specified by a field in an implicit register.

For target-precision-constrained rounding and denormalization rounding, the input is the precise intermediate value. For functionally-constrained rounding, the input is a source operand.

## Permissible Set

Rounding selects a value from the permissible set. A permissible set is a set of values, and not representations; thus, for DFP, the selection of a member from the cohort is considered to be performed after rounding. A permissible set differs from the values representable in a particular format in the following ways:

1. A permissible set does not include infinity. Infinity is handled as a special case.
2. For target-precision-constrained rounding, the permissible set is considered to have an unbounded exponent range.
3. For denormalization rounding, the permissible set is limited to the values representable in a particular format.
4. For LOAD FP INTEGER, the permissible set contains only integral values.
5. For QUANTIZE, the permissible set is similar to LOAD FP INTEGER, containing only those values which are integral multiples of the requested quantum.
6. For REROUND, the permissible set contains only those values which can be represented within the requested precision.

## Selection of Candidates

If a member of the permissible set is equal in value to the input value, then that member is selected; otherwise, two adjacent candidates with the same sign as the input value are chosen from the permissible set. One candidate, called TZ (toward zero), is the member of the permissible set nearest to and smaller in magnitude than the input value; the other candidate, called AZ (away from zero), is the member of the permissible set nearest to and larger in magnitude than the input value. Which of the two candidates is selected depends on the rounding method.

### Ties

Three rounding methods depend on a condition called a “tie.” This condition exists when the two candidates are equidistant from the input value.

### Voting Digit and Common-Rounding-Point View

Two rounding methods depend on the value of the voting digit of each candidate. (Each “digit” is an integral value from zero to one less than the radix. Thus, a BFP digit is one bit, an HFP digit is four bits, and a DFP digit is a value from zero to nine.) The voting digit is the units digit of the significand when considered in the common-rounding-point view.

Without changing the value of a floating-point number, the significand may be viewed with the implied radix point in different positions, provided a corresponding adjustment is made to the exponent. In the common-rounding-point view, an implied radix point (called the common rounding point) and an associated exponent are selected for the input value and the two candidates, TZ and AZ. The common-rounding point is selected to satisfy the following requirements:

1. The input value and the two candidates all have the same exponent.
2. The significand of TZ is equal to the significand of the input value truncated at the rounding point.
3. The significand of AZ is one greater in magnitude than the significand of TZ.

## Rounding Methods

**Round to nearest with ties to even:** The candidate nearest to the input value is selected. In case of

a tie, the candidate selected is the one whose voting digit has an even value.

**Round toward 0:** The candidate that is smaller in magnitude is selected.

**Round toward  $+\infty$ :** The candidate that is algebraically greater is selected.

**Round toward  $-\infty$ :** The candidate that is algebraically less is selected.

**Round to nearest with ties away from 0:** The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one that is larger in magnitude.

**Round to nearest with ties toward 0:** The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one that is smaller in magnitude.

**Round away from 0:** The candidate that is greater in magnitude is selected.

**Round to prepare for shorter precision:** For a BFP or HFP permissible set, the candidate selected is the one whose voting digit has an odd value. For a DFP permissible set, the candidate that is smaller in magnitude is selected, unless its voting digit has a value of either 0 or 5; in that case, the candidate that is greater in magnitude is selected.

### Programming Notes:

1. The two candidates are defined as: “nearest to and smaller” and “nearest to and larger”. Note that the simpler definition, “the two closest values,” is incorrect, as it is possible that the two closest values to the input value can be on the same side (toward zero). To illustrate this, Figure 9-9 on page 9-14 gives an example of rounding the integer value 10,000,003 to DFP short. Several members in the permissible set near this value are shown in three views: left-units view, right-units view, and integer view. The fourth column shows the distance of each member from the input value. In this example, the four closest members are all smaller in magnitude than the input value. Although the example is shown using DFP, corresponding examples can be shown for both BFP and HFP. In the extreme case, the number of members in the permissible

set which are closer than candidate AZ, is 2, 10, and 16, for BFP, DFP, and HFP, respectively.

2. Except for rounding methods using the voting digit, rounding can normally be considered to be performed using values independent of the representation and the view. Figure 9-10 on page 9-15 is an example, using the instruction LOAD FP INTEGER, to illustrate the concepts of different representations, views, rounding point, common-rounding-point view, and voting digit. In the example, the input value (source operand) is 29.5 and the two candidates are 29 and 30. The figure shows all three of these values using the left-units, right-units, and common-rounding-point views in both decimal and binary representations. Note that as shown in the left-units and right-units view columns, the rightmost digit is odd for both TZ and AZ. (But as represented in all BFP formats, these values would have an even rightmost digit; and as represented in DFP formats, these values could have an even or odd rightmost digit, depending on the quantum.) The voting digit can be identified in the common-rounding-point view as the digit to the immediate left of the rounding point. In both the decimal and binary representations, candidate TZ has an odd voting digit and candidate AZ has an even voting digit.

LOAD FP INTEGER produces consistent results between decimal and binary for all five rounding methods currently supported by the BFP instruction, including the round-to-nearest-with-ties-to even rounding method. If a program were to emulate a BFP version of the LOAD FP INTE-

GER function for the additional three rounding methods, this would also be the case for two of these rounding methods. This is not always the case, however, for the round-to-prepare-for-shorter-precision rounding method. Figure 9-11 on page 9-15 shows results of LOAD FP INTEGER for several input values for all eight rounding methods. Only in the round-to-prepare-for-shorter-precision method are the results different for decimal and binary.

3. An example of LOAD ROUNDED (long to short DFP) is shown in Figure 9-12 on page 9-15. In this example, the integer 99,999,995 is rounded from DFP long to DFP short. The cohort for candidate TZ in this case, has only one member and is odd. The cohort of candidate AZ has seven members, one of which is odd and the other six are even. The common-rounding-point view makes it clear that in this case, candidate AZ should be considered to be even.
4. The rightmost digit and the voting digit of a candidate are not necessarily the same digit. Figure 9-13 on page 9-15 and Figure 9-14 on page 9-16 give two examples using the instruction REROUND (long DFP). In both examples, the requested significance is one (Result Digits=1). The input value is 95 in the first example and 150 in the second example. Note that candidate AZ in the first example is the same value as candidate TZ in the second example. In the first example, this member is considered to be even, and in the second example it is considered to be odd.

Value in Permissible Set			Distance from 10000003	Notes
Left-Units View	Right-Units View	Integer View

## Explicit Rounding Methods

The floating-point-support instruction CONVERT HFP TO BFP includes an M<sub>3</sub> modifier field which can specify any of five rounding methods. One HFP instruction (CONVERT TO FIXED); three BFP instructions (CONVERT TO FIXED, DIVIDE TO INTEGER, and LOAD FP INTEGER); and five DFP instructions (CONVERT TO FIXED, LOAD FP INTEGER, LOAD ROUNDED, QUANTIZE, and REROUND) also include either an M<sub>3</sub> modifier field or a similar M<sub>4</sub> modifier field. The handling of an M<sub>3</sub> or M<sub>4</sub> value of zero depends on the type of instruction. For BFP instructions, an M<sub>3</sub> or M<sub>4</sub> value of zero causes rounding to be performed according to the current BFP rounding mode specified in the FPC register. For DFP instructions, an M<sub>3</sub> or M<sub>4</sub> value of zero causes rounding to be performed according to the current DFP rounding mode specified in the FPC register. Most floating-point-support and HFP instructions treat an M<sub>3</sub> or M<sub>4</sub> of zero the same as 5, that is, round toward zero. For PFPO, a zero in the rounding field causes the current DFP rounding mode to be used.

## Summary of Rounding Action

Figure 9-15 on page 9-16 summarizes the rounding action for floating-point-support (FPS), BFP, DFP, and HFP instructions.

Instruction	Rounding Action For			
	FPS Inst.	HFP Inst.	BFP Inst.	DFP Inst.
ADD	—	—	CBRM	CDRM
ADD NORMALIZED	—	GD	—	—
ADD UNNORMALIZED	—	GD	—	—
CONVERT BFP TO HFP	E	—	—	—
CONVERT FROM FIXED	—	RTZ	CBRM	CDRM
CONVERT HFP TO BFP	M	—	—	—
CONVERT TO FIXED	—	M	MB	MD
DIVIDE	—	RTZ	CBRM	CDRM

Figure 9-15. Comparison of Rounding Action

Instruction	Rounding Action For			
	FPS Inst.	HFP Inst.	BFP Inst.	DFP Inst.
DIVIDE TO INTEGER	—	—	MB	—
HALVE	—	RTZ	—	—
LOAD FP INTEGER	—	RTZ	MB	MD
LOAD ROUNDED	—	RNTA	CBRM	MD
MULTIPLY	—	RTZ	CBRM	CDRM
MULTIPLY AND ADD	—	RTZ	CBRM	—
MULTIPLY AND ADD UNNORMALIZED	—	RTZ	—	—
MULTIPLY AND SUBTRACT	—	RTZ	CBRM	—
MULTIPLY UNNORMALIZED	—	RTZ	—	—
PERFORM FLOATING-POINT OPERATION	MBD	—	—	—
QUANTIZE	—	—	—	MD
REROUND	—	—	—	MD
SQUARE ROOT	—	RNTA	CBRM	—
SUBTRACT	—	—	CBRM	CDRM
SUBTRACT NORMALIZED	—	GD	—	—
SUBTRACT UNNORMALIZED	—	GD	—	—

### Explanation:

CBRM	Rounded according to current BFP rounding mode.
CDRM	Rounded according to current DFP rounding mode.
E	Result is exact, no rounding is required.
GD	Round using a guard digit; see the instruction definition. This is almost, but not quite, round toward 0.
M	Rounding is specified by a modifier field in the instruction. Five rounding methods are supported.
MB	Rounding is specified by a modifier field in the instruction. Five rounding methods are supported; current BFP rounding mode can also be specified.
MD	Rounding is specified by a modifier field in the instruction. Eight rounding methods are supported; current DFP rounding mode can also be specified.
MBD	Rounding is specified by a field in general register 0. Eight rounding methods are supported; current BFP rounding mode and current DFP rounding mode can also be specified.
RNTA	Round to nearest with ties away from 0.
RTZ	Round toward 0.

Figure 9-15. Comparison of Rounding Action (Continued)

## IEEE Exceptions

This section defines handling of IEEE exceptions for most IEEE computational operations. For some instructions the action may differ from the general rules; including, for example, a special control to sup-

press recognition of the IEEE-inexact exception. These differences are described in the individual instruction descriptions.

The action taken for each IEEE exception is controlled by a mask bit in the FPC register. When an IEEE exception is recognized, one of two actions is taken:

- If the corresponding mask bit in the FPC register is zero, a default action, called IEEE nontrap action, is taken, as specified for each condition, and the corresponding flag bit in the FPC register is set to one. Program execution then continues normally.
- If the corresponding mask bit in the FPC register is one, an action, called IEEE trap action, is taken for that exception, a program interruption for a data exception occurs, and the operation is suppressed or completed, depending on the exception, and the data-exception code (DXC) assigned for that exception is provided. For PFPO, a control bit in GRO can select alternate exception handling, where overflow or underflow can be reflected by completion with a distinguished condition code, avoiding the interruption.

## Concurrent IEEE Exceptions

IEEE-inexact exceptions can coincide with IEEE-overflow or IEEE-underflow exceptions.

When the action for IEEE overflow (or underflow) is a nontrap action, the IEEE-overflow (or IEEE-underflow) flag bit in the FPC register is set to one and then the action for IEEE inexact (which could be a nontrap or trap action) occurs.

When the action for IEEE overflow (or underflow) is a trap action, the inexact exception is not recognized and not reported directly; instead, the DXC is set to indicate whether the result is exact, inexact and truncated, or inexact and incremented.

## IEEE Invalid Operation

An IEEE-invalid-operation exception is recognized when, in the execution of an IEEE computational operation, any of the following occurs:

1. An SNaN is encountered in an IEEE computational operation.

2. A QNaN is encountered in an unordered-signaling comparison (COMPARE AND SIGNAL with a QNaN operand).
3. An IEEE difference is undefined (addition of infinities of opposite sign, or subtraction of infinities of like sign).
4. An IEEE product is undefined (zero times infinity).
5. An IEEE quotient is undefined (DIVIDE instruction with both operands zero or both operands infinity).
6. A BFP remainder is undefined (DIVIDE TO INTEGER with a dividend of infinity or a divisor of zero).
7. A BFP square root is undefined (negative non-zero operand).
8. Any other IEEE computational operation whose result is either undefined or not representable in the target format.

**IEEE-Invalid-Operation Nontrap Action:** IEEE-invalid-operation nontrap action occurs when the IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is zero. The operation is completed and the IEEE-invalid-operation flag bit in the FPC register is set to one. The result of the operation depends on the type of operation and the operands.

If the instruction performs a comparison, the comparison result is *unordered*.

If the instruction is one that produces an IEEE result and none of the operands is a NaN, the result is the default QNaN.

If the instruction is one that produces an IEEE result and one of the operands is a NaN, that operand becomes the result unchanged, except that an SNaN is first converted to the corresponding QNaN and, for DFP, NaNs are canonicalized.

**IEEE-Invalid-Operation Trap Action:** IEEE-invalid-operation trap action occurs when the IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 80 hex.

## **IEEE Division-By-Zero**

An IEEE-division-by-zero exception is recognized when in IEEE division the divisor is zero and the dividend is a nonzero finite number.

***IEEE-Division-By-Zero Nontrap Action:*** IEEE-division-by-zero nontrap action occurs when the IEEE-division-by-zero exception is recognized and the IEEE-division-by-zero mask bit in the FPC register is zero. The operation is completed and the IEEE-division-by-zero flag bit in the FPC register is set to one. The result is set to an infinity with a sign that is the exclusive or of the dividend and divisor signs.

***IEEE-Division-By-Zero Trap Action:*** IEEE-division-by-zero trap action occurs when the IEEE-division-by-zero exception is recognized and the IEEE-division-by-zero mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 40 hex.

## **IEEE Overflow**

An IEEE-overflow exception is recognized for an IEEE target when the precision-rounded value of an IEEE computational operation is greater in magnitude than the largest finite number (Nmax) representable in the target format.

***IEEE-Overflow Nontrap Action:*** IEEE-overflow nontrap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-overflow flag bit in the FPC register is set to one. The result of the operation depends on the sign of the precise intermediate value and on the effective rounding method:

1. For all round-to-nearest methods and round-away-from-0, the result is infinity with the sign of the precise intermediate value.
2. For round-toward-0 and round-to-prepare-for-shorter-precision, the result is the largest finite number of the format, with the sign of the precise intermediate value.
3. For round toward  $+\infty$ , the result is  $+\infty$ . if the sign is plus, or it is the negative finite number with the largest magnitude if the sign is minus.

4. For round toward  $-\infty$ , the result is the largest positive finite number if the sign is plus or  $-\infty$ . if the sign is minus.

***IEEE-Overflow Trap Action:*** IEEE-overflow trap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value and the exception is reported as a program interruption for a data exception with DXC 20, 28, or 2C hex, depending on whether the delivered value is exact, inexact and truncated, or inexact and incremented, respectively.

The result of the operation is derived from the precision-rounded value, the scale factor, and, for DFP, on the scaled preferred quantum. The value of the scale factor depends on the type of operation and operand format. The scaled preferred quantum for a particular operation is equal to the preferred quantum for that operation divided by the scale factor for that operation.

The delivered value is equal to the precision-rounded value divided by the scale factor. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected.

## **IEEE Underflow**

An IEEE-underflow exception is recognized for an IEEE target when the tininess condition exists and either: (1) the IEEE-underflow mask bit in the FPC register is zero and the denormalized value is inexact, or (2) the IEEE-underflow mask bit in the FPC register is one.

The tininess condition exists when the precise intermediate value of an IEEE computational operation is nonzero and smaller in magnitude than the smallest normal number (Nmin) representable in the target format.

The denormalized value is inexact if it is not equal to the precise intermediate value.

***IEEE-Underflow Nontrap Action:*** IEEE-underflow nontrap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-underflow flag bit in the FPC register is set to one. The result is set to the denormalized value. For DFP targets, the cohort member with the smallest quantum is selected.

**IEEE-Underflow Trap Action:** IEEE-underflow trap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value and the exception is reported as a program interruption for a data exception with DXC 10, 18, or 1C hex, depending on whether the delivered value is exact, inexact and truncated, or inexact and incremented, respectively.

The result of the operation is derived from the precision-rounded value, the scale factor and, for DFP, on the scaled preferred quantum. The value of the scale factor depends on the type of operation and operand format. The scaled preferred quantum for a particular operation is equal to the preferred quantum for that operation divided by the scale factor for that operation.

The result is set to the precision-rounded value divided by the scale factor. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected.

## IEEE Inexact

An IEEE-inexact exception is recognized when, for an IEEE computational operation, an inexact condition exists, recognition of the exception is not suppressed, and neither IEEE-overflow trap action nor IEEE-underflow trap action occurs.

An inexact condition exists when the rounded intermediate value differs from the precise intermediate value. The condition also exists when IEEE-overflow nontrap action occurs. When the inexact condition exists, the delivered value and the result are said to be inexact.

Even though an inexact condition exists, the IEEE-inexact exception is not recognized if recognition of the exception is suppressed or if IEEE overflow or IEEE underflow trap action occurs. When an inexact condition exists and the conditions for an IEEE-overflow trap action or IEEE-underflow trap action also

apply, the trap action takes precedence and the inexact condition is reported in the DXC.

**IEEE-Inexact Nontrap Action:** IEEE-inexact nontrap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value and the IEEE-inexact flag bit in the FPC register is set to one. For DFP targets, except for QUANTIZE and REROUND, the cohort member with the smallest quantum is selected.

When an IEEE-inexact nontrap action and another IEEE nontrap action coincide, the operation is completed using the result specified for the other exception and the flag bits for both exceptions are set to one.

**IEEE-Inexact Trap Action:** IEEE-inexact trap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is one. The operation is completed and the exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated or inexact and incremented, respectively.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value. For DFP targets, the cohort member with the smallest quantum is selected.

When the IEEE-inexact trap action coincides with an IEEE nontrap action, the operation is completed using the result specified for the IEEE nontrap action, the flag bit for the nontrap exception is set to one, and the IEEE-inexact trap action takes place.

## Programming Notes:

1. IEEE traps are reported by means of a program interruption for a data exception with a data-exception code.<sup>1</sup> The use of data exception provides the application program with a convenient interface since this exception is one of the original 15 exceptions in the System/360 architecture and is supported by most control programs that support the z/Architecture.

1. PFPO provides an option for trap action without the program interruption.

2. ANSI/IEEE Standard 754-1985 includes recommendations for the trap handler. When a system traps, the trap handler should be able to determine:
  - a. Which exception(s) were recognized on this operation.
  - b. The kind of operation that was being performed.
  - c. The destination's format.
  - d. For overflow, underflow, and inexact exceptions, the correctly rounded result, including information that might not fit in the destination's format.
  - e. For invalid-operation and divide-by-zero exceptions, the operand values.

Items a and d are supplied as part of the interruption action. Items b, c, and e can be obtained starting with the instruction address in the old PSW and from this finding the instruction (which indicates the operation and format) and then the operands.

3. The description of underflow is one of the most difficult parts of the standard to understand. This is because:
  - a. The condition is described as two “correlated events” — “tininess” and “loss of accuracy”.
  - b. For tininess, ANSI/IEEE Standard 754-1985 provides two options for detection: “after rounding” or “before rounding”.
  - c. For loss of accuracy, ANSI/IEEE Standard 754-1985 provides two options for detection: “denormalization loss” or “inexact result”.
  - d. Implementation of the trap is optional.
  - e. The conditions to signal underflow are different depending on whether or not the trap is taken.

Each of the above items is discussed below.

- a. Tininess refers to a nonzero number strictly between  $\pm N_{\min}$ . (All subnormal numbers are in this range.) Loss of accuracy means that the result cannot be represented exactly.
- b. Detection of tininess after or before rounding differs only for the case when “rounding”

would increase the magnitude of the result to exactly  $\pm N_{\min}$ . It must be noted, however, that the action which ANSI/IEEE Standard 754-1985 here calls “rounding” is not the rounding to produce the delivered result but rounding to compute an intermediate value having the precision of the result but “as though the exponent range were unbounded”. In fact, it is possible that the delivered result may not be tiny even though the intermediate value “after rounding” is tiny.

The option selected in the z/Architecture (and the Power architecture) is to detect tininess before rounding.

- c. The difference between detection of loss of accuracy as a denormalization loss or as an inexact result can best be understood by considering three intermediate values: (1) the precise intermediate value, which has unbounded precision and unbounded exponent range, (2) the precision-rounded value, which is obtained by rounding the precise intermediate value to the precision of the target format but with unbounded exponent range, and (3) the denormalized value, which is obtained by rounding the precise intermediate value to the precision and exponent range of the target format. An inexact condition is said to exist when the denormalized value (3) differs from the precise intermediate value (1). A denormalization loss is said to exist when the denormalized value (3) differs from the precision-rounded value (2). The two options differ in the case when the denormalized value (3) is equal to the precision-rounded value (2) but these are not equal to the precise intermediate value (1). Although ANSI/IEEE Standard 754-1985 uses the term “denormalization loss”, this condition includes a case in which the delivered result is normal.

The option selected in the z/Architecture (and the Power architecture) is to detect “loss of accuracy” as an inexact result.

- d. Although ANSI/IEEE Standard 754-1985 does not require traps to be implemented for underflow or the other IEEE exceptions, it does state that “with each exception should be associated a trap under user control”. Since it also defines “should” as “that which is strongly recommended as being in keep-

ing with the intent of the standard”, the z/Architecture provides traps by means of program interruptions.

- e. When the underflow trap is enabled, underflow is to be signaled when tininess is detected regardless of loss of accuracy. When the underflow trap is not enabled, the underflow flag bit is to be set only when both tininess and loss of accuracy have been detected. Add and subtract can result in tiny or inexact results, but not both. Thus, when underflow is disabled, add and subtract never set the underflow flag bit.

## IEEE Same-Radix Format Conversion

The instructions LOAD LENGTHENED and LOAD ROUNDED perform conversions of data between the short, long, and extended formats, where the source and target operands are in the same radix. (For mixed-radix conversions, see PFPO.) For BFP and DFP formats, same-radix conversion involves adjustments to both the significand and the biased exponent. Conversion to a narrower format requires rounding of the significand and an IEEE-inexact exception may result.

When converting to a narrower format, adjustment of the biased exponent causes IEEE underflow if the resultant left-units-view (LUV) exponent would be less than the minimum LUV exponent ( $E_{min}$ ), or IEEE overflow if the resultant LUV exponent would be greater than the maximum LUV exponent ( $E_{max}$ ) for the new format.

### Programming Notes:

1. When a NaN is converted to a narrower format, for BFP the appropriate number of payload bits on the right (or for DFP, the appropriate number of payload digits on the left) are simply dropped with no indication. This is unlike the conversion of nonzero numbers, where the loss of nonzero significand digits causes an IEEE-inexact exception. Thus, programs which encode NaN payloads for specific purposes must ensure that the distinguishing bits (or digits) are placed in the left part of the payload for BFP and in the right part of the payload for DFP.

2. For BFP, converting a NaN to a narrower format cannot turn the NaN into an infinity because an SNaN either causes an interruption or turns into a QNaN, and all QNaNs have a leftmost fraction bit of one.

## IEEE Comparison

Comparisons are always exact and cannot cause IEEE-overflow or IEEE-underflow exceptions.

Comparison ignores the sign of zero, that is,  $+0$  equals  $-0$ .

Infinities with like sign compare equal, that is,  $+\infty$  equals  $+\infty$ , and  $-\infty$  equals  $-\infty$ .

A NaN compares as *unordered* with any other operand, whether a finite number, an infinity, or another NaN, including itself.

Two sets of instructions are provided: COMPARE and COMPARE AND SIGNAL. In the absence of QNaNs, these instructions work the same. These instructions work differently only when both of the following are true:

- Neither operand of the instruction is an SNaN
- At least one operand of the instruction is a QNaN

In this case, COMPARE simply sets condition code 3, but COMPARE AND SIGNAL recognizes the IEEE-invalid-operation exception. If any operand is an SNaN, both instructions recognize the IEEE-invalid-operation exception.

The action when the IEEE-invalid-operation exception is recognized depends on the IEEE-invalid-operation mask bit in the FPC register. If the mask bit is zero, then the instruction execution is completed by setting condition code 3, and the IEEE-invalid-operation flag in the FPC register is set to one. If the mask bit is one, then the exception is reported as a program interruption for a data exception with DXC 80 hex (IEEE invalid operation).

**Programming Note:** A compiler can select either COMPARE or COMPARE AND SIGNAL for a comparison, depending on whether it is desired that a QNaN to be recognized as an exception.

## Condition Codes for IEEE Instructions

For those operations which set the condition code to indicate the value of an IEEE result, condition codes 0, 1, and 2 are set to indicate that the result is a zero of either sign, less than zero, or greater than zero, respectively. The condition-code setting depends only on an inspection of the rounded result. For comparison operations, condition codes 0, 1, and 2 indicate equal, low, or high, respectively. These settings are the same as for the HFP instructions.

Condition code 3 can also be set. After an arithmetic operation, condition code 3 indicates a NaN result of either sign. After a comparison, it indicates that a NaN was involved in the comparison (the unordered condition). See Figure 9-16.

CC	Arithmetic	Comparison
0	$\pm 0$	Equal
1	$<0$	Low
2	$>0$	High
3	$\pm \text{NaN}$	Unordered

Figure 9-16. Condition Codes

## Instructions

The floating-point-support instructions and their mnemonics and operation codes are listed in Figure 9-17 on page 9-23. The figure indicates, in the column labeled "Characteristics", the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All floating-point-support instructions are subject to the AFP-register-control bit, bit 45 of control register 0. The AFP-register-control bit must be one when an AFP register is specified as an operand location; otherwise, an AFP-register data exception, DXC 1, is recognized.

Mnemonics for the floating-point instructions have an R as the last letter when the instruction is in the RR, RRE, or RRF format. Certain letters are used for floating-point instructions to represent operand-format length, as follows:

D Long  
E Short  
X Extended

**Note:** In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using LOAD (short), for example, LER is the mnemonic and  $R_1, R_2$  the operand designation.

### Programming Notes:

1. The following additional floating-point-support instruction is available when the decimal-floating-point facility is installed:
  - SET DFP ROUNDING MODE (SRNMT)
2. The following additional floating-point-support instructions are available when the floating-point-support-sign-handling facility is installed:
  - COPY SIGN (CPSDR)
  - LOAD COMPLEMENT (LCDFR)
  - LOAD NEGATIVE (LNDFR)
  - LOAD POSITIVE (LPDFR)
3. The following additional floating-point-support instructions are available when the FPR-GPR-transfer facility is installed:
  - LOAD FPR FROM GR (LDGR)
  - LOAD GR FROM FPR (LGDR)
4. The following additional floating-point-support instructions are available when the IEEE-exception-simulation facility is installed:
  - LOAD FPC AND SIGNAL (LFAS)
  - SET FPC AND SIGNAL (SFASR)
5. The following additional floating-point-support instructions are available when the long-displacement facility is installed:
  - LOAD (LDY, LEY)
  - STORE (STDY, STEY)
6. The following additional floating-point-support instruction is available when the PFPO facility is installed:
  - PERFORM FLOATING POINT OPERATION (PFPO)

## CONVERT BFP TO HFP

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
Op Code		R <sub>1</sub> R <sub>2</sub>
0	16 24	28 31

Mnemonic	Op Code	Operands
THDER	'B358'	Short BFP operand, long HFP result
THDR	'B359'	Long BFP operand, long HFP result

The second operand (the source operand) is converted from the binary-floating-point (BFP) format to the hexadecimal-floating-point (HFP) format, and the normalized result is placed at the first-operand location. The sign and magnitude of the source operand are tested to determine the setting of the condition code.

For numeric operands, the sign of the result is the sign of the source operand. If the source operand has a sign bit of one and all other operand bits are zeros, the result also is a one followed by all zeros.

When, for THDR, the characteristic of the result would be negative, the result is made all zeros but with the same sign as that of the source operand, and condition code 1 or 2 is set to indicate the sign of the source operand.

When, for THDR, the characteristic of the hexadecimal intermediate result is too large to fit into the target format, the result is set to all ones (that is, the largest-in-magnitude representable finite number) but with the same sign as that of the source operand, and condition code 3 is set.

See Figure 9-18 for a detailed description of the results of this instruction.

### Resulting Condition Code:

- 0 Source was zero
- 1 Source was less than zero
- 2 Source was greater than zero
- 3 Special case

### Program Exceptions:

- Data with DXC 1, AFP register

### Programming Notes:

1. The BFP-to-HFP conversion instructions are summarized in Figure 9-19.
2. CONVERT BFP TO HFP (THDER) converts BFP operands in the short format to HFP operands in

the long format, rather than converting short to short, to retain full precision. Using this long HFP result subsequently as a short operand requires no extra conversion steps.

Source Operand (a)	Results
$-\infty \leq a < -H_{\max}$	T(-H <sub>max</sub> ), cc3
$-H_{\max} \leq a \leq -H_{\min}$	T(r), cc1
$-H_{\min} < a < 0$	T(-0) <sup>1</sup> , cc1
-0	T(-0), cc0
+0	T(+0), cc0
$0 < a < +H_{\min}$	T(+0) <sup>2</sup> , cc2
$+H_{\min} \leq a \leq +H_{\max}$	T(r), cc2
$+H_{\max} < a \leq +\infty$	T(+H <sub>max</sub> ), cc3
NaN	T(+H <sub>max</sub> ), cc3

**Explanation:**

<sup>1</sup> Condition code 1 is set to indicate the source was less than zero.  
<sup>2</sup> Condition code 2 is set to indicate the source was greater than zero.  
 ccn Condition code is set to n.  
 r The value derived when the BFP source value a is converted to the HFP format. This result is always exact.  
 H<sub>max</sub> Largest (in magnitude) representable number in the target HFP format.  
 H<sub>min</sub> Smallest (in magnitude) representable normalized number in the target HFP format.  
 T(x) The value x is placed at the target operand location.

Figure 9-18. Results: CONVERT BFP TO HFP

Instruction	Mnemonic	Source		Target			Overflow, Underflow Possible
		Format	Significant Bits	Format	Significant Bits	Result	
CONVERT BFP TO HFP	THDER	BFP short	24	HFP long	53-56	Exact	No
	THDR	BFP long	53	HFP long	53-56	Exact	Yes
CONVERT HFP TO BFP	TBEDR	HFP long	53-56	BFP short	24	Rounded	Yes
	TBDR	HFP long	53-56	BFP long	53	Rounded	No

Figure 9-19. Summary of BFP-to/from-HFP Conversion Instructions

## CONVERT HFP TO BFP

TBDR 'B351' Long HFP operand, long BFP result

Mnemonic R<sub>1</sub>,M<sub>3</sub>,R<sub>2</sub> [RRF]

Op Code	M <sub>3</sub>	///	R <sub>1</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic Op Code Operands  
TBEDR 'B350' Long HFP operand, short BFP result

The second operand (the source operand) is converted from the hexadecimal-floating-point (HFP) format to the binary-floating-point (BFP) format, and the result rounded according to the rounding method specified by the M<sub>3</sub> field is placed at the first-operand location. The sign and magnitude of the source oper-

and are tested to determine the setting of the condition code.

The M<sub>3</sub> field contains a modifier specifying a rounding method, as follows:

#### M<sub>3</sub> Effective Rounding Method

- 0 Round toward 0
- 1 Round to nearest with ties away from 0
- 4 Round to nearest with ties to even
- 5 Round toward 0
- 6 Round toward +∞
- 7 Round toward -∞

A modifier other than 0, 1, or 4-7 is invalid. See the section “Rounding Methods” on page 9-13.

The sign of the result is the sign of the second operand. If the second operand has a sign bit of one and all other operand bits are zeros, the result also is a one followed by all zeros.

See Figure 9-20 on page 9-26 for a detailed description of the results of this instruction.

The M<sub>3</sub> field must designate a valid modifier; otherwise, a specification exception is recognized.

#### Resulting Condition Code:

- 0 Source was zero
- 1 Source was less than zero
- 2 Source was greater than zero
- 3 Special case

#### Program Exceptions:

Source Operand (a)	Results for Rounding Method Specified in M <sub>3</sub>				
	Round to Nearest with Ties away from 0	Round to Nearest with Ties to Even	Round toward 0	Round toward +∞	Round toward -∞
a < -Nmax	T(-∞), cc3	T(-∞), cc3	T(-Nmax), cc3	T(-Nmax), cc3	T(-∞), cc3
+Nmax < a	T(+∞), cc3	T(+∞), cc3	T(+Nmax), cc3	T(+∞), cc3	T(+Nmax), cc3

Figure 9-20. (Part 2 of 2) Results: CONVERT HFP to BFP

- Data with DXC 1, AFP register
- Specification

#### Programming Notes:

1. The HFP-to-BFP conversion instructions are summarized in Figure 9-19 on page 9-25.
2. Conversion to short BFP data requires HFP operands in the long format; a short HFP operand should be extended to long by ensuring that the right half of the register is cleared. Thus, the entire register should be cleared before loading a short HFP operand into it for conversion to BFP. This avoids unrepeatable rounding errors in the BFP result due to data left over from previous use.

Source Operand (a)	Results
a < -Nmax	See Part 2 of this figure.
-Nmax ≤ a ≤ -Nmin	T(r), cc1
-Nmin < a ≤ -Dmin	T(d), cc1
-Dmin < a < 0	T(d) <sup>1</sup> , cc1
-0	T(-0), cc0
+0	T(+0), cc0
0 < a < +Dmin	T(d) <sup>2</sup> , cc2
+Dmin ≤ a < +Nmin	T(d), cc2
+Nmin ≤ a ≤ +Nmax	T(r), cc2
+Nmax < a	See Part 2 of this figure.

Figure 9-20. (Part 1 of 2) Results: CONVERT HFP to BFP

Source Operand (a)	Results for Rounding Method Specified in M <sub>3</sub>				
	Round to Nearest with Ties away from 0	Round to Nearest with Ties to Even	Round toward 0	Round toward +∞	Round toward -∞
<b>Explanation:</b>					
1	Condition code 1 is set for this case, even when the rounded result is zero.				
2	Condition code 2 is set for this case, even when the rounded result is zero.				
ccn	Condition code is set to n.				
d	The denormalized value derived when the HFP source value a is rounded to the format of the target using the rounding method specified in the M <sub>3</sub> field.				
r	The value derived when the HFP source value a is rounded to the format of the target using the rounding method specified in the M <sub>3</sub> field.				
Dmin	Smallest (in magnitude) representable subnormal number in the target BFP format.				
Nmax	Largest (in magnitude) representable finite number in the target BFP format.				
Nmin	Smallest (in magnitude) representable normal number in the target BFP format.				
T(x)	The value x is placed at the target operand location.				

*Figure 9-20. (Part 2 of 2) Results: CONVERT HFP to BFP*

## COPY SIGN

CPSDR	$R_1, R_3, R_2$	[RRF]
'B372'	$R_3$	$R_1$ $R_2$
0	16	20 24 28 31

The second operand is placed at the first-operand location with the sign bit set to the sign of the third operand. The first, second, and third operands are each in a 64-bit floating-point register. The sign bit of the second operand and bits 1-63 of the third operand are ignored.

**Condition Code:** The code remains unchanged.

## ***Program Exceptions:***

- Data with DXC 1, AFP register
  - Operation (if the floating-point-support-sign-handling facility is not installed)

## Programming Notes:

1. COPY SIGN is radix independent and can be used to operate on HFP, BFP, or DFP operands or even to copy the sign between operands having different radixes.
  2. Since the sign is in the same bit position (the left-most bit) in all widths for all radixes, the third operand can be a short, long, or extended format.

3. COPY SIGN can be used in conjunction with LOAD (LDR) to copy the sign of an operand in the extended format.

# EXTRACT FPC

EFPC	R <sub>1</sub>	[RRE]	
'B38C'		R <sub>1</sub>	
0	16	24	28 31

The contents of the FPC (floating-point-control) register are placed in bit positions 32-63 of the general register designated by R<sub>1</sub>. Bit positions 0-31 of the general register remain unchanged.

**Condition Code:** The code remains unchanged.

***IEEE Exceptions:*** None.

## ***Program Exceptions:***

- Data with DXC 2, BFP instruction

## LOAD

Mnemonic1	R <sub>1</sub> , R <sub>2</sub>	[RR]
Op Code	R <sub>1</sub>	R <sub>2</sub>

0            8            12    15

Mnemonic1	Op Code	Operands
LER	'38'	Short
LDR	'28'	Long

Mnemonic2 R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic2 Op Code Operands  
LXR 'B365' Extended

Mnemonic3 R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RX]

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
0	8	12	16	20 31

Mnemonic3 Op Code Operands  
LE '78' Short  
LD '68' Long

Mnemonic4 R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RXY]

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	DL <sub>2</sub>	DH <sub>2</sub>	Op Code
0	8	12	16	20	32	40 47

Mnemonic4 Op Code Operands  
LEY 'ED64' Short  
LDY 'ED65' Long

The second operand is placed unchanged at the first-operand location.

The operation is performed without inspecting the contents of the second operand; no arithmetic exceptions are recognized.

For LXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

The displacement for LE and LD is treated as a 12-bit unsigned binary integer. The displacement for LEY and LDY is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Access (fetch, operand 2 of LE, LD, LEY, and LDY)
- Data with DXC 1, AFP register
- Operation (LEY and LDY, if the long-displacement facility is not installed)
- Specification (LXR only)

## LOAD COMPLEMENT

LCDFR R<sub>1</sub>,R<sub>2</sub> [RRE]

'B373'		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

The second operand is placed at the first-operand location with the sign bit inverted. Both the first and second operands are each in a 64-bit floating-point register.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)

#### Programming Notes:

- LOAD COMPLEMENT (LCDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.
- LOAD COMPLEMENT (LCDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

## LOAD FPC

LFPC D<sub>2</sub>(B<sub>2</sub>) [S]

'B29D'	B <sub>2</sub>	D <sub>2</sub>
0	16	20 31

The four-byte second operand in storage is loaded into the FPC (floating-point-control) register.

Bits corresponding to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

#### Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC 2, BFP instruction
- Specification

**Programming Note:** When the architectural mode of a CPU is changed without resetting the FPC register (by means of the set architecture signal-processor order, for example) the entire contents of the FPC register are preserved. This is true even when some of these bits are associated with a facility which is not available in both architectural modes. Checking for unsupported bit positions of the FPC register is performed independently of the current architectural mode of the CPU; thus, it is always safe to restore the FPC register from a value previously saved on this CPU, even after the architectural mode has changed.

## LOAD FPC AND SIGNAL

LFAS	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B2BD'	B <sub>2</sub> D <sub>2</sub>

16      20      31

First, bits 0-4 of byte 1 of the floating-point-control (FPC) register at the beginning of the operation are preserved to be used as signaling flags. Next, the contents of the source operand are placed in the FPC register; then the flags in the FPC register are set to the logical OR of the signaling flags and the source flags. Finally, the conditions for simulated-IEEE-exception trap action are examined.

The source operand is the second operand in storage.

If any signaling flag is one and the corresponding source mask is also one, simulated-IEEE-exception trap action occurs. The data-exception code (DXC) in the FPC register is updated to indicate the specific cause of the interruption and a data-exception program interruption occurs at completion of the instruction execution. The DXC for the interruption is shown in Figure 9-21.

If no signaling flag is enabled, the DXC in the FPC register remains as loaded from the source and instruction execution completes with no trap action.

See Figure 9-22 for a detailed description of the result of this instruction.

Bits in the source operand that correspond to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC 3, DFP instruction
- Data with DXC for simulated IEEE exception
- Operation (if the IEEE-exception-simulation facility is not installed)
- Specification

Enabled <sup>1</sup> Signaling Flags Bit 0 1 2 3 4	DXC (Binary)
1 - - - -	1000 0011
0 1 - - -	0100 0011
0 0 1 - -	0010 w011
0 0 0 1 -	0001 w011
0 0 0 0 1	0000 1011

**Explanation:**

DRM DFP rounding mode  
DXC Data-exception code  
OR Set to the logical OR of signaling flags and source flags.  
S Set to the contents of the corresponding field in the source operand.  
Trap Simulated-IEEE-exception trap action. This action occurs when the logical AND of the signaling flags and source masks is nonzero.  
Xg DXC for simulated IEEE exception. See Figure 9-21

Figure 9-22. Result: LFAS and SFASR

**Programming Notes:**

1. The IEEE-exception-simulation instructions (LOAD FPC AND SIGNAL and SET FPC AND SIGNAL) are provided to facilitate program simulation of IEEE operations not provided directly in the machine. These instructions permit the simulation routine to restore the caller's masks, flags, and rounding modes; and, when appropriate, to simulate IEEE exceptions, including traps when enabled.
2. On entry, the simulation routine should first save the FPC register contents (containing the caller's masks, flags, and rounding modes), disable all traps, clear all flags, establish appropriate rounding modes, and then perform the necessary floating-point operations. Finally, the routine should set the current flags (called signaling flags) appropriately, and invoke either LOAD FPC AND SIGNAL or SET FPC AND SIGNAL.
3. When a program interruption for a data exception occurs, and both bit 6 and 7 of the DXC are ones, it indicates to the trap handler that the interruption was caused by a simulated-IEEE-exception trap action. The remaining bits of the DXC indicate the type of IEEE exception. Additional information required by the trap handler can be determined by the contents of a trap-information block, located by convention, at a fixed offset from the location where the instruction causing the trap resides.

The following shows an example of this scheme. The block and the code below are inserted at an appropriate place where a trap can occur. In this example, the LOAD FPC AND SIGNAL instruction is used, and the caller's FPC register contents are at the location, SAVEDFPC.

The trap information block can contain the designation of floating-point registers and general registers containing the information (or addresses of the information) for the following types of items:

- a. The operation being simulated
- b. Format and values of source operands

- c. Format and value of the result
- d. Any additional information useful to the trap handler.

**LOAD FPR FROM GR**

LDGR	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B3C1'		R <sub>1</sub> R <sub>2</sub>
0	16	24 28 31

The second operand is placed at the first-operand location. The second operand is in a general register, and the first operand is in a floating-point register.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- Operation (if the FPR-GR-transfer facility is not installed)

**LOAD GR FROM FPR**

LGDR	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B3CD'		R <sub>1</sub> R <sub>2</sub>
0	16	24 28 31

The second operand is placed at the first-operand location. The second operand is in a floating-point register, and the first operand is in a general register.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- Operation (if the FPR-GR-transfer facility is not installed)

**LOAD NEGATIVE**

LNDFR	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B371'		R <sub>1</sub> R <sub>2</sub>
0	16	24 28 31

The second operand is placed at the first-operand location with the sign bit set to one. Both the first and

second operands are each in a 64-bit floating-point register.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)

**Programming Notes:**

1. LOAD NEGATIVE (LNDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.
2. LOAD NEGATIVE (LNDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

## LOAD POSITIVE

LPDFR	R <sub>1</sub> , R <sub>2</sub>	[RRE]
'B370'		R <sub>1</sub> R <sub>2</sub>

The second operand is placed at the first-operand location with the sign bit set to zero. Both the first and second operands are each in a 64-bit floating-point register.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)

**Programming Notes:**

1. LOAD POSITIVE (LPDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.
2. LOAD POSITIVE (LPDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

## LOAD ZERO

Mnemonic	R <sub>1</sub>	[RRE]
Op Code		R <sub>1</sub>

Mnemonic	Op Code	Operands
LZER	'B374'	Short
LZDR	'B375'	Long
LZXR	'B376'	Extended

All bits of the first operand are set to zeros.

For LZXR, The R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Data with DXC 1, AFP register
- Specification (LZXR only)

**Programming Note:** LOAD ZERO sets all bits of a register to zeros, which produces a positive zero value in the BFP, DFP, and HFP formats. For DFP, addition of an all-zero value to any normal value, X, normalizes X.

## PERFORM FLOATING-POINT OPERATION

PFPO	[E]
'010A'	15

The operation specified by the function code in general register 0 is performed and the condition code is set to indicate the result. When there are no exceptional conditions, condition code 0 is set. When an IEEE nontrap exception is recognized, condition code 1 is set. When an IEEE trap exception with alternate action is recognized, condition code 2 is set. A 32-bit return code is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged.

The PERFORM FLOATING-POINT OPERATION (PFPO) instruction is subject to the AFP-register-control bit, bit 45 of control register 0. For PFPO to be executed successfully, the AFP-register-control bit

must be one; otherwise, an AFP-register data exception, DXC 1, is recognized.

Bit 32 of general register 0 is the test bit. When bit 32 is zero, the function specified by bits 33-63 of general register 0 is performed; each field in bits 33-63 must be valid and the combination must be a valid and installed function; otherwise a specification exception is recognized. When bit 32 is one, the function specified by bits 33-63 is not performed but, instead, the condition code is set to indicate whether these bits specify a valid and installed function; the condition code is set to 0 if the function is valid and installed, or to 3 if the function is invalid or not installed. This will be useful if additional functions are assigned in the future. This definition is written as if the test bit is zero except when stated otherwise.

Bits 33-39 of GR0 specify the operation type. Only one operation type is currently defined: 01, hex, is PFPO Convert Floating-Point Radix.

For the PFPO-convert-floating-point-radix operation, other fields in general register 0 include first-operand format, second operand format, control flags, and rounding method. For the PFPO-convert-floating-point-radix operation, the second operand is converted to the format of the first operand and placed at the first-operand location, a return code is placed in bits 32-63 of general register 1, and the condition code is set to indicate whether an exceptional condition was recognized.

The first and second operands are in implicit floating-point registers. The first operand is in FPR0 (paired with FPR2 for extended). The second operand is in FPR4 (paired with FPR6 for extended).

## General Register 0 (GR0)

The following figures summarize fields and bits in general register 0 (GR0).

GR0 Bit(s)	Name and Detail
0-31	Reserved/Ignored
32	Test Bit
33-39	PFPO-operation-type code
40-47	PFPO-operand-format code for operand 1
48-55	PFPO-operand-format code for operand 2
56	Inexact-suppression control
57	Alternate-exception-action control
58-59	Target-radix-dependent controls
60-63	PFPO rounding method

Figure 9-23. Fields in GR0 for PFPO

Xo IEEE-overflow exception.  
Xu IEEE-underflow exception.  
Xx IEEE-inexact exception.

Figure 9-28. Basic PFPO Functions (GR0 bits 33-55)

**Inexact-Suppression Control:** Bit 56 of general register 0 is the inexact-suppression control. When the inexact-suppression control is zero, IEEE-inexact exceptions are recognized and reported in the normal manner. When the inexact-suppression control is one, IEEE-inexact exceptions are not recognized. The inexact-suppression control has no effect on the DXC; that is, the DXC for IEEE-overflow or IEEE-underflow exceptions along with the detail for exact, inexact and truncated, or inexact and incremented, is reported according to the actual condition.

Figure 9-28. Basic PFPO Functions (GR0 bits 33-55)

**Alternate-Exception-Action Control:** Bit 57 of general register 0 is the alternate-exception-action control. The setting of this control affects the action taken for IEEE-overflow and IEEE-underflow trap exceptions.

When the alternate-exception-action control is zero, IEEE-overflow and IEEE-underflow trap exceptions are reported in the normal manner. That is, the appropriate data exception code (DXC) is placed in byte 2 of the floating-point control register, the operation is completed, and a program interruption for a data exception occurs. (As part of the program interruption, the DXC is stored at location 147.) This is called an *IEEE trap exception with normal action*.

When the alternate-exception-action control is one, the DXC is placed in byte 2 of the floating-point control register, the operation is completed, condition code 2 is set, and program execution continues with the next sequential instruction. (There is no program interruption and the DXC is not stored at location 147.) This is called an *IEEE trap exception with alternate action*.

**HFP-Overflow Control:** Bit 58 of general register 0 is the HFP-overflow control. When the HFP-overflow control is zero, an HFP-overflow condition is reported as an IEEE-invalid-operation exception and is subject to IEEE-invalid-operation mask. When the HFP-overflow control is one, an HFP-overflow condition is reported as an IEEE-overflow exception and is subject to the IEEE-overflow mask.

The HFP-overflow control is defined only for HFP targets; when other than an HFP target is specified, this bit must be zero.

**HFP-Underflow Control:** For HFP targets, bit 59 of general register 0 is the HFP alternate underflow control. When the HFP-underflow control is zero, HFP underflow causes the result to be set to a true zero with the same sign as the source and underflow is not reported. (The result in this case is inexact and subject to the inexact-suppression control.) When the HFP-underflow control is one, the condition is reported as an IEEE-underflow exception and is subject to the IEEE-underflow mask.

Bit 59 of general register 0 is defined only for HFP and DFP targets; when a BFP target is specified, this bit must be zero.

**DFP Preferred Quantum Control (DPQC):** For DFP targets, bit 59 of general register 0 is the DFP preferred quantum control (DPQC). For radix conversion with DFP targets, if the delivered value is inexact, the cohort member with the smallest quantum is selected; if the delivered value is exact, selection depends on the value of bit 59 of general register 0, the DFP preferred quantum control (DPQC). When the delivered value is exact and the DPQC bit is zero, the cohort member with the largest quantum is selected. When the delivered value is exact and the DPQC bit is one, the preferred quantum is one and the cohort member with the quantum closest to one is selected.

## Return Code

Regardless of what condition code is set, and independent of whether the test bit is one, a 32-bit return code is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged. A return code is also placed in general register 1 when a program interruption occurs for an IEEE trap exception that completes; general register 1 is not updated when a program interruption occurs for an IEEE trap exception that suppresses. Thus, general register 1 is updated on a program interruption for IEEE-overflow, IEEE-underflow, and IEEE-inexact trap exceptions, but is not updated on a program interruption for an IEEE-invalid-operation trap exception.

Except where otherwise specified, the return code is a value of zero.

## Sign Preservation

For PFPO convert floating-point radix, the sign of the result is the same as the sign of the source. The only exception to this is when the source is a NaN and the target is HFP; in this case, the result is the largest representable number in the target HFP format (Hmax) with the sign set to plus.

## Preferred Quantum

For radix conversion with DFP targets, if the delivered value is inexact, the cohort member with the smallest quantum is selected; if the delivered value is exact, selection depends on the value of bit 59 of general register 0, the DFP preferred quantum control (DPQC). When the delivered value is exact and the DPQC bit is zero, the cohort member with the largest quantum is selected. When the delivered value is exact and the DPQC bit is one, the preferred

quantum is one and the cohort member with the quantum closest to one is selected.

## NaN Conversion

When converting between DFP and BFP, the sign of the NaN is always preserved, and the value of the payload is preserved, when possible. If the value of the source payload exceeds the maximum value of the target payload, the target is set to the default QNaN, but with the same sign as the source.

When traps are disabled, an SNaN is converted to the corresponding QNaN, and the payload is preserved, when possible; that is, SNaN(x) is converted to QNaN(x), where x is the value of the payload. For DFP, both QNaN(0) and SNaN(0) can be represented; but in BFP, there is a representation for QNaN(0), but not for SNaN(0).

## Scaled Value and Signed Scaling Exponent ( $\Omega$ ) for PFPO

When, for the PFPO-convert-floating-point-radix operation, IEEE-overflow trap action or IEEE-underflow trap action occurs, the scaled value is computed using the following steps:

$$\Psi = b^\Omega$$

$$z = g \div \Psi$$

Where  $\Omega$  is the signed scaling exponent, b is the target radix (2, 10, or 16),  $\Psi$  is the scale factor, g is the precision-rounded value, and z is the scaled value.

The signed scaling exponent ( $\Omega$ ) is selected to make the magnitude of the value of the scaled result (z) lie in the range:

$$1 \leq |z| < b.$$

The value of the signed scaling exponent ( $\Omega$ ), treated as a 32-bit signed binary integer, is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged.

The scaled value is used as the delivered value and is placed in the result location. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected. (But it should be noted that for all currently supported conversions, the result is always inexact, so the cohort member with the smallest quantum is selected.) For BFP targets, there are no redundant representations, there is

only one member in a cohort. For HFP targets, the result is normalized.

## HFP Values

Unnormalized HFP values are accepted on input, but all HFP results are normalized. If an HFP result would be less than the smallest (in magnitude) representable normalized number, an HFP underflow condition exists.

## HFP Overflow and Underflow for PFPO

For an HFP target of a PFPO-convert-floating-point-radix operation, the handling of overflow and underflow conditions is controlled by the HFP-overflow control and the HFP-underflow control, respectively.

**HFP Overflow:** An HFP-overflow condition exists when an HFP target precision's largest number (Hmax) is exceeded in magnitude by the precision-rounded value. That is, when the characteristic of a normalized HFP result would exceed 127 and the fraction is not zero.

When the HFP-overflow control is zero, HFP-overflow is reported as an IEEE-invalid-operation exception and is subject to the IEEE-invalid-operation mask in the FPC register. This is called an *HFP-overflow-as-IEEE-invalid-operation condition*.

When the HFP-overflow control is one, HFP overflow is reported as an IEEE-overflow exception and is subject to the IEEE-overflow mask in the FPC register. This is called an *HFP-overflow-as-IEEE-overflow condition*.

**HFP Underflow:** An HFP-underflow condition exists when the precision-rounded value is nonzero and less in magnitude than the HFP target precision's smallest normalized number, Hmin. That is, when the characteristic of a normalized HFP result would be less than zero and the fraction is not zero. The result is set to a true zero with the same sign as the source. Reporting of the HFP-underflow condition is subject to the HFP-underflow control. The result in this case, however, is inexact and is subject to the controls for that condition.

When the HFP-underflow control is zero, the HFP-underflow condition is not reported.

When the HFP-underflow control is one, HFP underflow is reported as an IEEE-underflow exception and is subject to the IEEE-underflow mask in the FPC

register. This is called an *HFP-underflow-as-IEEE-underflow condition*.

## IEEE Exceptions for PFPO

Except where otherwise stated, the following sections on IEEE exceptions apply to both BFP and DFP.

**IEEE Invalid Operation:** An IEEE-invalid-operation exception is recognized when any of the following occurs:

1. An SNaN is encountered in an IEEE source.
2. In an IEEE-to-HFP conversion, a NaN or an infinity is encountered in the IEEE source.
3. An HFP-overflow-as-IEEE-invalid-operation condition exists.

IEEE-invalid-operation exceptions are recognized as either IEEE-invalid-operation nontrap exceptions or IEEE-invalid-operation trap exceptions.

### IEEE-Invalid-Operation Nontrap Action

IEEE-invalid-operation nontrap action occurs when an IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is zero. The operation is completed, the IEEE-invalid-operation flag bit in the FPC register is set to one, and condition code 1 is set. The result is as follows:

- When the target is IEEE and the source is an IEEE SNaN, the result is the source NaN converted to the corresponding canonical QNaN in the target format.
- When the target is HFP and the source is an IEEE NaN, the result is the largest representable number in the target HFP format (Hmax) with the sign set to plus.
- When the target is HFP and the source is an IEEE infinity, the result is Hmax with the same sign as the source.
- When an HFP-overflow-as-IEEE-invalid-operation condition exists, the result is Hmax with the same sign as the source.

### IEEE-Invalid-Operation Trap Action

IEEE-invalid-operation trap action occurs when an IEEE-invalid-operation exception is recognized and

the IEEE-invalid-operation mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 80 hex.

**IEEE Overflow:** For IEEE targets, an IEEE-overflow exception is recognized when the precision-rounded value is greater in magnitude than the largest finite number (Nmax) representable in the target format. For HFP targets, an IEEE-overflow exception is recognized when the HFP-overflow condition exists and the HFP-overflow control is one.

### IEEE-Overflow Nontrap Action

IEEE-overflow nontrap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-overflow flag bit in the FPC register is set to one. For IEEE targets, the result of the operation depends on the sign of the precise intermediate value and on the effective rounding method:

1. For all round-to-nearest methods and round-away-from-0, the result is infinity with the sign of the precise intermediate value.
2. For round-toward-0 and round-to-prepare-for-shorter-precision, the result is the largest finite number of the format, with the sign of the precise intermediate value.
3. For round toward  $+\infty$ , the result is  $+\infty$  if the sign is plus, or it is the negative finite number with the largest magnitude if the sign is minus.
4. For round toward  $-\infty$ , the result is the largest positive finite number if the sign is plus or  $-\infty$  if the sign is minus.

For HFP targets, the result is set to the largest representable number in the target HFP format (Hmax) with the same sign as the source.

Additional action depends on whether there is also an IEEE-inexact exception.

When IEEE-overflow nontrap action occurs and no IEEE-inexact exception has been recognized, the IEEE-overflow flag bit in the FPC register is set to one and condition code 1 is set. (This case can occur only when the inexact-suppression control is one.)

When both IEEE-overflow nontrap action and IEEE-inexact nontrap action occur, the IEEE-overflow and IEEE-inexact flag bits in the FPC register are set to ones and condition code 1 is set.

When IEEE-overflow nontrap action and IEEE-inexact trap action occur, the condition code is not set, the IEEE-overflow flag bit in the FPC register is set to one, and the IEEE-inexact exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated or inexact and incremented, respectively.

### **IEEE-Overflow Trap Action**

IEEE-overflow trap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value; placing the value of the signed scaling exponent ( $\Omega$ ), treated as a 32-bit signed binary integer in bits 32-63 of general register 1; and setting DXC 20, 28, or 2C hex, depending on whether the delivered value is exact, inexact and truncated, or inexact and incremented, respectively.

For DFP targets, the delivered value is always inexact and the cohort member with the smallest quantum is selected.

Additional action depends on the value of the alternate-exception-action control.

When the alternate-exception-action control is zero, the condition code is not set and the exception is reported as a program interruption for a data exception.

When the alternate-exception-action control is one, condition code 2 is set and no program interruption occurs.

**IEEE Underflow:** For IEEE targets, an IEEE-underflow exception is recognized when the tininess condition exists and either: (1) the IEEE-underflow mask bit in the FPC register is zero and the denormalized value is inexact, or (2) the IEEE-underflow mask bit in the FPC register is one.

The tininess condition exists when the precise intermediate value of an IEEE computational operation is nonzero and smaller in magnitude than the smallest

normal number (Nmin) representable in the target format.

The denormalized value is inexact if it is not equal to the precise intermediate value.

For HFP targets, an IEEE-underflow exception is recognized when the HFP-underflow condition exists and the HFP-underflow control is one.

### **IEEE-Underflow Nontrap Action**

IEEE-underflow nontrap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-underflow flag bit in the FPC register is set to one.

For IEEE targets, the result is set to the denormalized value. For DFP targets, the cohort member with the smallest quantum is selected.

For HFP targets, the result is set to a true zero with the same sign as the source.

Additional action depends on whether there is also an IEEE-inexact exception.

When IEEE-underflow nontrap action occurs and no IEEE-inexact exception has been recognized, the IEEE-underflow flag bit in the FPC register is set to one and condition code 1 is set. (This case can occur only when the inexact-suppression control is one.)

When both IEEE-underflow nontrap action and IEEE-inexact nontrap action occur, the IEEE-underflow and IEEE-inexact flag bits in the FPC register are set to ones and condition code 1 is set.

When IEEE-underflow nontrap action and IEEE-inexact trap action occur, the condition code is not set, the IEEE-underflow flag bit in the FPC register is set to one, and the IEEE-inexact trap exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated or inexact and incremented, respectively.

### **IEEE-Underflow Trap Action**

IEEE-underflow trap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value; placing the value of the signed scaling exponent ( $\Omega$ ), treated as a 32-bit signed binary integer in bits 32-63 of general register 1; and setting DXC 10, 18, or 1C hex, depending on whether the result is exact, inexact and truncated, or inexact and incremented, respectively.

For DFP targets, the delivered value is always inexact and the cohort member with the smallest quantum is selected.

Additional action depends on the value of the alternate-exception-action control.

When the alternate-exception-action control is zero, the condition code is not set and the exception is reported as a program interruption for a data exception.

When the alternate-exception-action control is one, condition code 2 is set and no program interruption occurs.

**IEEE Inexact:** An IEEE-inexact exception is recognized when, for a PFPO-convert-floating-point-radix operation, an inexact condition exists, recognition of the exception is not suppressed, and neither IEEE-overflow trap action nor IEEE-underflow trap action occurs.

An inexact condition exists when the rounded intermediate value differs from the precise intermediate value. The condition also exists when IEEE-overflow nontrap action occurs.

Even though an inexact condition exists, the IEEE-inexact exception is not recognized if the inexact-suppression control is one or if IEEE overflow or IEEE underflow trap action occurs. When an inexact condition exists and the conditions for an IEEE-overflow trap action or IEEE-underflow trap action also apply, the trap action takes precedence and the inexact condition is reported in the DXC.

### IEEE-Inexact Nontrap Action

IEEE-inexact nontrap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value, condition code 1 is set, and the IEEE-inex-

act flag bit in the FPC register is set to one. For DFP targets, the cohort member with the smallest quantum is selected.

When an IEEE-inexact nontrap action and another IEEE nontrap action coincide, the operation is completed using the result specified for the other exception and the flag bits for both exceptions are set to one, and condition code 1 is set.

### IEEE-Inexact Trap Action

IEEE-inexact trap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is one. The operation is completed, the condition code is not set, and the exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated or inexact and incremented, respectively.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value. For DFP targets, the cohort member with the smallest quantum is selected.

When the IEEE-inexact trap action coincides with an IEEE nontrap action, the operation is completed using the result specified for the IEEE nontrap action, the flag bit for the nontrap exception is set to one, and the IEEE-inexact trap action takes place.

#### **Resulting Condition Code (when test bit is zero):**

- 0 Normal result
- 1 Nontrap exception
- 2 Trap exception with alternate action
- 3 --

#### **Resulting Condition Code (when test bit is one):**

- 0 Function is valid
- 1 --
- 2 --
- 3 Function is invalid

#### **IEEE Exceptions:**

- Invalid operation
- Overflow
- Underflow
- Inexact

#### **Program Exceptions:**

- Data with DXC 1, AFP register
- Data with DXC for IEEE exception
- Operation (if the PFPO facility is not installed)
- Specification

### Programming Notes:

1. The PFPO-convert-floating-point-radix operation performs “correct rounding”; that is, the result is accurately obtained from the precise intermediate value using the effective rounding method. This is in contrast to some radix conversion programs, which may produce results with larger rounding errors.
  2. Note that a value of zero in the rounding method field (GR0 bits 60-63) specifies rounding according to the current DFP rounding mode (FPC 3.1-3) regardless of whether the target is DFP, BFP, or HFP.
  3. If the program does not supply a default QNaN (payload = zero) as a source, then its presence as a result indicates that the machine either created a new QNaN or the program attempted to convert a payload which was too large for this format.
  4. If the program restricts payloads to values within the smallest payload capacity of any format to be converted to, then payloads are preserved across radix conversions.
  5. In the absence of suppression, bits 32-63 of general register 1 are always set to a return code, even though, in most cases, the return code is zero. Future extensions of PFPO may make more use of nonzero return codes. With the current definition, the only nonzero return codes are set for IEEE-overflow trap exceptions and IEEE-underflow trap exceptions. In this case, the value of the signed scaling exponent ( $\Omega$ ), is placed in bits 32-63 of general register 1. For IEEE-inexact trap exceptions, the return code is set to zero, thus indicating that no scaling has occurred.
  6. To display a value in scientific notation, many programming languages, calculators, and spread
- sheets use the letter e (or E) to separate the significand from the exponent. This is referred to as e-form notation. In this document, e-form notation, along with other forms of conventional numeric notation, is used to represent a value without regard to quantum. To indicate that both value and quantum are being represented, a variation of e-form notation, called q-form notation, is used. In q-form notation, the letter q replaces the letter e and the value shown after q is the right-units-view exponent, that is, the base 10 logarithm of the quantum. Thus, for example, the seven members of the cohort for the value 1e6 in the DFP short format are: 1q6, 10q5, 100q4, 1000q3, 10000q2, 100000q1, and 1000000q0.
7. As an example of the distinction between e-form and q-form notation, consider the representation of the members of the cohort of zero. The DFP short format, for example, can represent 198 exact powers of 10, ranging in value from 1e-101 to 1e96; but can represent only 192 values for a quantum, ranging from 1e-101 to 1e90. Thus, the 192 members of the cohort for zero range from 0q-101 to 0q90.
  8. The effect of the DFP preferred quantum control is shown in Figure 9-29.

Rounded Intermediate Value	Result If Inexact	Result If Exact and DPQC = 0	Result If Exact and DPQC = 1
0	0q-101	0q90	0q0
0.125	1250000q-7	125q-3	125q-3
1	1000000q-6	1q0	1q0
10	1000000q-5	1q1	10q0
100	1000000q-4	1q2	100q0
1000	1000000q-3	1q3	1000q0
9999	9999000q-3	9999q0	9999q0
10000	1000000q-2	1q4	10000q0
10001	1000100q-2	10001q0	10001q0
1e5	1000000q-1	1q5	100000q0

## PFPO Action Figures

Symbol	Meaning
Caa	Alternate-exception-action control
Cho	HFP-overflow control
Chu	HFP-underflow control
Csx	Inexact-suppression control
Hmax	The largest (in magnitude) representable number in this HFP format with the same sign as the source.
Ho	HFP-overflow condition
Hu	HFP-underflow condition
IMi	IEEE-invalid-operation mask
Figure 9-30. Symbols Used in PFPO Action Figures	
IMo	IEEE-overflow mask
IMu	IEEE-underflow mask
IMx	IEEE-inexact mask
N	No
N'	No (true by virtue of conditions to the left of this column)
PI	Program interruption
Rx	Inexact-result condition
SFi	IEEE-invalid-operation flag
SFo	IEEE-overflow flag
SFu	IEEE-underflow flag
SFx	IEEE-inexact flag
Xi	IEEE-invalid-operation exception
Xo	IEEE-overflow exception
Xu	IEEE-underflow exception
Y	Yes
Y'	Yes (true by virtue of conditions to the left of this column)
+Hmax	Hmax with a plus sign
Tz	True zero with the same sign as the source.

## SET BFP ROUNDING MODE

SRNM	D <sub>2</sub> (B <sub>2</sub> )	[S]
'B299'	B <sub>2</sub>	D <sub>2</sub>

0 16 20 31

The BFP rounding-mode bits are set from the second-operand address.

The second-operand address is not used to address data; instead, the BFP rounding-mode bits in the FPC register are set with bits 62 and 63 of the address.

Bits other than 62 and 63 of the second-operand address are ignored.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**

- Data with DXC 2, BFP instruction

## SET DFP ROUNDING MODE

SRNMT	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B2B9'	B <sub>2</sub> D <sub>2</sub>

16      20      31

The DFP rounding-mode bits are set from the second-operand address.

The second-operand address is not used to address data; instead, the DFP rounding-mode bits in the FPC register are set with bits 61-63 of the address.

Bits other than 61-63 of the second-operand address are ignored.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Operation (if the decimal-floating-point-rounding facility is not installed)

## SET FPC

SFPC	R <sub>1</sub>	[RRE]
0	'B384'	R <sub>1</sub>

16      24      28      31

The contents of bit positions 32-63 of the general register designated by R<sub>1</sub> are placed in the FPC (floating-point-control) register.

All of bits 32-63 corresponding to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration. Bits 0-31 of the general register are ignored.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**

- Data with DXC 2, BFP instruction
- Specification

**Programming Note:** When the architectural mode of a CPU is changed without resetting the FPC register (by means of the set architecture signal-processor order, for example) the entire contents of the FPC register are preserved. This is true even when some of these bits are associated with a facility which is not available in both architectural modes. Checking for unsupported bit positions of the FPC register is performed independently of the current architectural mode of the CPU; thus, it is always safe to restore the FPC register from a value previously saved on this CPU, even after the architectural mode has changed.

## SET FPC AND SIGNAL

SFASR	R <sub>1</sub>	[RRE]
0	'B385'	R <sub>1</sub>

16      24      28      31

First, bits 0-4 of byte 1 of the floating-point-control (FPC) register at the beginning of the operation are preserved to be used as signaling flags. Next, the contents of the source operand are placed in the FPC register; then the flags in the FPC register are set to the logical OR of the signaling flags and the source flags. Finally, the conditions for simulated-IEEE-exception trap action are examined.

The source operand is in bits 32-63 of the general register designated by R<sub>1</sub>; bits 0-31 of the general register are ignored.

If any signaling flag is one and the corresponding source mask is also one, simulated-IEEE-exception trap action occurs. The data-exception code (DXC) in the FPC register is updated to indicate the specific cause of the interruption and a data-exception program interruption occurs at completion of the instruction execution. The DXC for the interruption is shown in Figure 9-21 on page 9-29.

If no signaling flag is enabled, the DXC in the FPC register remains as loaded from the source and instruction execution completes with no trap action.

See Figure 9-22 on page 9-29 for a detailed description of the result of this instruction.

Bits in the source operand that correspond to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for simulated IEEE exception
- Operation (if the IEEE-exception-simulation facility is not installed)
- Specification

#### Programming Notes:

1. See also the programming notes under LOAD FPC AND SIGNAL.
2. Bits 0-31 of the general register designated by the R<sub>1</sub> field are reserved for future extension and should be set to zeros.

## STORE

Mnemonic R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RX]

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
0	8	12	16	20

31

Mnemonic	Op Code	Operands
STE	'70'	Short
STD	'60'	Long

Mnemonic2 R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RXY]

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	DL <sub>2</sub>	DH <sub>2</sub>	Op Code
0	8	12	16	20	32	40

Mnemonic2 Op Code Operands

STEY	'ED66'	Short
STDY	'ED67'	Long

The first operand is placed unchanged in storage at the second-operand location.

The displacement for STE and STD is treated as a 12-bit unsigned binary integer. The displacement for STEY and STDY is treated as a 20-bit signed binary integer.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Access (store, operand 2)
- Data with DXC 1, AFP register
- Operation (STEY and STDY, if the long-displacement facility is not installed)

## STORE FPC

STFPC D<sub>2</sub>(B<sub>2</sub>) [S]

'B29C'	B <sub>2</sub>	D <sub>2</sub>
0	16	20

31

The contents of the FPC (floating-point-control) register are placed in storage at the second-operand location.

The operand is four bytes in length. All 32 bits of the FPC register are stored.

**Condition Code:** The code remains unchanged.

#### IEEE Exceptions:

None.

#### Program Exceptions:

- Access (store, operand 2)
- Data with DXC 2, BFP instruction

page 9-46 shows the floating-point instructions other than PFPO which perform radix conversion.

---

## Summary of All Floating-Point Instructions

Figures 9-36 through 9-42 on the following pages show mnemonics for all floating-point instructions (except for PFPO) arranged in various categories of operand format and type of operation. Figure 9-36 shows those instructions which operate on the FPC register. Figure 9-37 on page 9-44 shows the floating-point instructions which have all operands in the same format (same radix and same length), including those FPS (floating-point support) instructions which operate on floating-point operands in a radix-independent manner. Figure 9-38 on page 9-45 and Figure 9-39 on page 9-45 show the floating-point instructions in which all operands are in the same radix but not all of the same length. Figure 9-40 on page 9-45 and Figure 9-41 on page 9-46 show the floating-point instructions in which the source or the result is in a general register. Figure 9-42 on

Instruction Name	Mnemonic	Type
EXTRACT FPC	EFFPC	BFP
LOAD FPC	<b>LFFPC</b>	BFP
LOAD FPC AND SIGNAL	<b>LFAS</b>	DFP
SET BFP ROUNDING MODE	SRNM	BFP
SET DFP ROUNDING MODE	SRNMT	DFP
SET FPC	SFPC	BFP
SET FPC AND SIGNAL	SFASR	DFP
STORE FPC	<b>STFPC</b>	BFP

### Explanation:

	Mnemonics in <b>bold</b> indicate a register-and-storage operation.
BFP	The instruction is considered to be part of the BFP facility. An attempt to execute this instruction when the AFP-register-control bit is zero results in a BFP-instruction data exception, DXC 2.
DFP	The instruction is considered to be part of the DFP facility. An attempt to execute this instruction when the AFP-register-control bit is zero results in a DFP-instruction data exception, DXC 3.

Operation of Function Codes 0 and 1 .....	10-75		

This chapter includes all privileged and semiprivilaged instructions described in this publication, except the input/output instructions, which are described in “I/O Instructions” on page 14-1.

Privileged instructions may be executed only when the CPU is in the supervisor state. An attempt to execute a privileged instruction in the problem state generates a privileged-operation exception.

The semiprivilileged instructions are those instructions that can be executed in the problem state when certain authority requirements are met. An attempt to execute a semiprivilileged instruction in the problem state when the authority requirements are not met generates a privileged-operation exception or some other program-interruption condition depending on the particular requirement which is violated. Those requirements which cause a privileged-operation exception to be generated in the problem state are not enforced when execution is attempted in the supervisor state.

The control instructions and their mnemonics, formats, and operation codes are listed in Figure 10-1 on page 10-3. The figure also indicates which instructions are new in z/Architecture as compared to ESA/390, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

The instructions that are new in z/Architecture are indicated in Figure 10-1 by "N."

When the operands of an instruction are 32-bit operands, the mnemonic for the instruction does not include a letter indicating the operand length. If there is an instruction with the same name but with 64-bit operands, its mnemonic includes the letter "G." In Figure 10-1, when there is an instruction with 32-bit operands and another instruction with the same name but with "G" added in its mnemonic, the first instruction has "(32)" after its name, and the other instruction has "(64)" after its name.

For those control instructions which have special rules regarding the handling of exceptional situations, a section called "Special Conditions" is included. This section indicates the type of ending (suppression, nullification, or completion) only for those exceptions for which the ending may vary.

**Note:** In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For LOAD PSW, for example, LPSW is the mnemonic and D<sub>2</sub>(B<sub>2</sub>) the operand designation.

### Programming Notes:

1. The following additional control instructions are available when the DAT-enhancement facility is installed:

- COMPARE AND SWAP AND PURGE (CSPG)
- INVALIDATE DAT TABLE ENTRY

CSPG operates on a doubleword in storage, in contrast to the previously existing instruction COMPARE AND SWAP AND PURGE (CSP), which operates on a word in storage.

2. The long-displacement facility uses new instruction formats, named RSY, RXY, and SIY, to provide 20-bit signed displacements. In connection with the long-displacement facility, all previously existing control instructions of the RSE or RXE format are changed to be of format RSY or RXY, respectively, where the new formats differ from the old by using a previously unused byte, now named DH, in the instructions. When the long-displacement facility is installed, the displacement for an instruction operand address is formed by appending DH on the left of the previous displacement field, now named DL, of the instruction. When the long-displacement facility is not installed, eight zero bits are appended on the left of DL, and DH is ignored.

The following additional control instruction is available when the long-displacement facility is installed:

- LOAD REAL ADDRESS (LRAY)

The following additional control instructions are available when the ASN-and-LX-reuse facility is installed:

- EXTRACT PRIMARY ASN AND INSTANCE
- EXTRACT SECONDARY ASN AND INSTANCE
- PROGRAM TRANSFER WITH INSTANCE
- SET SECONDARY ASN WITH INSTANCE

3. The LOAD PAGE-TABLE-ENTRY ADDRESS control instruction is available when the DAT-enhancement facility 2 is installed.

4. The PERFORM TIMING FACILITY FUNCTION control instruction is available when the TOD-clock-steering facility is installed.

5. The MOVE WITH OPTIONAL SPECIFICATIONS control instruction is available when the move-with-optional-specifications facility is installed.

6. The PERFORM TOPOLOGY FUNCTION control instruction is available when the configuration-topology facility is installed.

**Explanation:**

- c Causes serialization and checkpoint synchronization.
- c<sup>2</sup> Causes serialization and checkpoint synchronization when the state entry to be unstacked is a program-call state entry.
- c<sup>3</sup> Causes serialization and checkpoint synchronization when the set-key control is one.
- \$ Causes serialization.
- A Access exceptions for logical addresses.
- A<sup>1</sup> Access exceptions; not all access exceptions may occur; see instruction description for details.
- B PER branch event.

Figure 10-1. Summary of Control Instructions (Part 2 of 4)

Name	Mne- monic	Characteristics	Op- code	Page
B <sub>1</sub>		B <sub>1</sub> field designates an access register in the access-register mode.		
B <sub>2</sub>		B <sub>2</sub> field designates an access register in the access-register mode.		
BP		B <sub>2</sub> field designates an access register when PSW bits 16 and 17 have the value 01 binary.		
B†		B <sub>1</sub> field designates an access register when bit 47 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 47 of GR0 is one, and bits 40-41 of GR0 are 01 binary.		
B‡		B <sub>2</sub> field designates an access register when bit 63 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 63 of GR0 is one, and bits 56-57 of GR0 are 01 binary.		
C		Condition code is set.		
CT		Configuration-topology facility.		
DE		DAT-enhancement facility.		
DM		Depending on the model, DIAGNOSE may generate various program exceptions and may change the condition code.		
D2		DAT-enhancement facility 2.		
E		E instruction format.		
ED		Enhanced-DAT facility.		
ES		Expanded-storage facility.		
FC		Designation of access registers depends on the function code of the instruction.		
G0		Instruction execution includes the implied use of general register 0.		
G2		Instruction execution includes the implied use of general register 2.		
GM		Instruction execution includes the implied use of multiple general registers: General registers 0 and 1 for MOVE WITH DESTINATION KEY, MOVE WITH SOURCE KEY, PERFORM TIMING FACILITY FUNCTION, and STORE SYSTEM INFORMATION. General registers 3, 4, and 14, and, when the ASN-and-LX-reuse facility is installed, general register 15 for PROGRAM CALL.		
II		Interruptible instruction.		
L		New condition code is loaded.		
LD		Long-displacement facility.		
MD		Designation of access registers in the access-register mode is model-dependent.		
MO		Move-with-optional-specifications facility.		
N		Instruction is new in z/Architecture as compared to ESA/390.		
N3		Instruction is new in z/Architecture and has been added to ESA/390.		
P		Privileged-operation exception.		
Q		Privileged-operation exception for semiprivilaged instructions.		
R <sub>1</sub>		R <sub>1</sub> field designates an access register in the access-register mode.		
R <sub>2</sub>		R <sub>2</sub> field designates an access register in the access-register mode.		
RA		Reusable-ASN-and-LX facility.		
RRE		RRE instruction format.		
RS		RS instruction format.		
RSY		RSY instruction format.		
RX		RX instruction format.		
RXY		RXY instruction format.		
S		S instruction format.		
SE		Special-operation, stack-empty, stack-specification, and stack-type exceptions.		
SF		Special-operation, stack-full, and stack-specification exceptions.		
SI		SI instruction format.		
SO		Special-operation exception.		
SP		Specification exception.		

Figure 10-1. Summary of Control Instructions (Part 3 of 4)

Name	Mne-monic	Characteristics	Op-code	Page
SS	SS instruction format.			
SSE	SSE instruction format.			
SSF	SSF instruction format.			
ST	PER storage-alteration event.			
SU	PER store-using-real-address event.			
SW	Special-operation exception and space-switch event.			
T	Trace exceptions (which include trace table, addressing, and low-address protection).			
TS	TOD-clock-steering facility.			
U <sub>1</sub>	R <sub>1</sub> field designates an access register unconditionally.			
U <sub>2</sub>	R <sub>2</sub> field designates an access register unconditionally.			
WE	Space-switch event.			
Z <sup>1</sup>	Additional exceptions and events for PROGRAM CALL (which include ASX-translation, EX-translation, LFX-translation, LSTE-sequence, LSX-translation, LX-translation, PC-translation-specification, special-operation, stack-full, stack-specification and subspace-replacement exceptions and space-switch event).			
Z <sup>2</sup>	Additional exceptions and events for PROGRAM TRANSFER (which include AFX-translation, ASX-translation, primary-authority, special-operation, and subspace-replacement exceptions and space-switch event).			
Z <sup>3</sup>	Additional exceptions for SET SECONDARY ASN (which include AFX translation, ASX translation, secondary authority, special operation and subspace replacement).			
Z <sup>4</sup>	Additional exceptions and events for PROGRAM RETURN (which include AFX-translation, ASTE-instance, ASX-translation, secondary-authority, special-operation, stack-empty, stack-operation, stack-specification, stack-type, and subspace-replacement exceptions and space-switch event).			
Z <sup>5</sup>	Additional exceptions for BRANCH AND STACK (which include special operation, stack full, and stack specification)			
Z <sup>6</sup>	Additional exceptions and events for PROGRAM TRANSFER WITH INSTANCE (which include AFX-translation, ASTE-instance, ASX-translation, primary-authority, special-operation, and subspace-replacement exceptions and space-switch event).			
Z <sup>7</sup>	Additional exceptions for SET SECONDARY ASN WITH INSTANCE (which include AFX translation, ASTE instance, ASX translation, secondary authority, special operation, and subspace replacement).			

Figure 10-1. Summary of Control Instructions (Part 4 of 4)

## BRANCH AND SET AUTHORITY

BSA	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B25A'	R <sub>1</sub> R <sub>2</sub>	0 16 24 28 31

If the dispatchable unit is in the base-authority state and the 24-bit or 31-bit addressing mode: bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are saved in the dispatchable-unit control table (DUCT); the PSW-key mask (PKM), PSW key, and problem-state bit also are saved in the DUCT; the PKM and PSW key are replaced using the contents of general register R<sub>1</sub>; the problem-state bit is set to one; bits 32 and 97-127 of the PSW are replaced using the contents of general register R<sub>2</sub>; and the dispatchable unit is placed in the reduced-

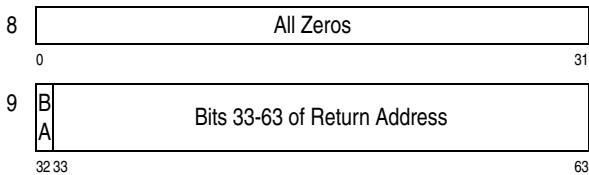

authority state. In the 64-bit addressing mode, the action is the same except that bits 64-127 of the current PSW are saved in the DUCT and replaced from general register R<sub>2</sub>, and bit 32 of the PSW is neither saved nor replaced.

If the dispatchable unit is in the reduced-authority state and the 24-bit or 31-bit addressing mode: bits 32 and 97-127 of the current PSW are saved in general register R<sub>1</sub> if R<sub>1</sub> is not zero; bits 32 and 97-127 of the PSW and the PKM, PSW key, and problem-state bit are replaced by values saved in the DUCT; and the dispatchable unit is placed in the base-authority state. In the 64-bit addressing mode, the action is the same except that bits 64-127 of the current PSW are saved in general register R<sub>1</sub> if R<sub>1</sub> is not zero, those bits in the PSW are replaced from the DUCT, and bit 32 of the PSW is neither saved nor replaced.

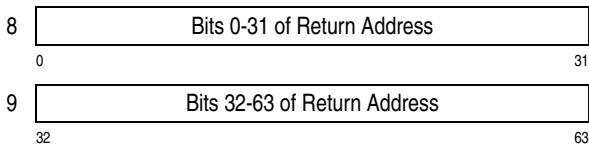

Words 5, 8, and 9 of the DUCT are used by this instruction. The contents of those words are as follows:

### In the 24-Bit or 31-Bit Addressing Mode

#### In the 64-Bit Addressing Mode

The fields in words 5, 8, and 9 of the DUCT are allocated as follows:

**PSW-Key Mask:** Bit positions 0-15 of word 5 contain the PSW-key mask (PKM), bits 32-47 of control register 3, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The PKM is restored to control register 3 by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

**PSW Key:** Bit positions 24-27 of word 5 contain the PSW key, bits 8-11 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The PSW key is restored to the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

**Reduced Authority (RA):** Bit 28 of word 5 indicates, when zero, that the dispatchable unit associated with the DUCT is in the base-authority state or, when one, that the dispatchable unit is in the reduced-authority state. Bit 28 is set to one by BRANCH AND SET AUTHORITY executed in the base-authority state, and it is set to zero by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

**Problem State (P):** Bit position 31 of word 5 contains the problem-state bit, bit 15 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the

base-authority state. The problem-state bit is restored to the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

**Basic Addressing Mode (BA):** In the 24-bit or 31-bit addressing mode, bit position 0 of word 9 contains the basic-addressing-mode bit, bit 32 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The basic-addressing-mode bit is restored to the PSW from the DUCT by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

**Return Address:** In the 24-bit or 31-bit addressing mode, bit positions 1-31 of word 9 contain bits 33-63 of the updated instruction address, bits 97-127 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. Bits 1-31 of word 9 of the DUCT are restored to bit positions 97-127 of the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state. In the 64-bit addressing mode, words 8 and 9 contain the updated instruction address saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The contents of words 8 and 9 are restored to bit positions 64-127 of the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

In the 24-bit or 31-bit addressing mode, all zeros are stored in word 8 when saving occurs in the base-authority state. In any addressing mode, all zeros are stored in bit positions 16-23, 29, and 30 of word 5 when saving occurs in the base-authority state.

All other fields in words 5, 8, and 9 remain unchanged when bit 28 of word 5 is set to zero in the reduced-authority state.

The fetch, store, and update references to the DUCT are single-access references and appear to be word concurrent as observed by other CPUs. The words of the DUCT are accessed in no particular order.

## Base-Authority Operation

When BRANCH AND SET AUTHORITY is executed in the base-authority state, as indicated by the reduced-authority bit (RA) in the DUCT being zero,  $R_2$  must be nonzero; otherwise, a special-operation exception is recognized.  $R_1$  may be zero or nonzero.

The contents of bit positions 32-63 of general register R<sub>1</sub> and of general register R<sub>2</sub> when the execution of

the instruction begins in the base-authority state are as follows:

$R_1$	Key Mask		Key	
32	48	56	60	63

#### In the 24-Bit or 31-Bit Addressing Mode

$R_2$	Ignored		
0	31		
B A	Bits 33-63 of Branch Address		

#### In the 64-Bit Addressing Mode

$R_2$	Bits 0-31 of Branch Address		
0	31		
32	Bits 32-63 of Branch Address		

In any addressing mode, the contents of bit positions 0-31 of general register  $R_1$  are ignored. In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general register  $R_2$  are ignored.

In the 24-bit or 31-bit addressing mode, PSW bits 32 and 97-127 are saved in word 9 of the DUCT, and zeros are stored in word 8. In the 64-bit addressing mode, PSW bits 64-127 are saved in words 8 and 9 of the DUCT. In any addressing mode, the PKM, the PSW key, and the problem-state bit are saved in word 5 of the DUCT, the RA bit in word 5 is set to one, and bits 16-23, 29, and 30 of word 5 are set to zeros.

Bits 56-59 of general register  $R_1$  are placed in bit positions 8-11 of the PSW as the new PSW key. In the problem state, the new PSW key must be authorized by the PKM; otherwise, if the new PSW key is not authorized, a privileged-operation exception is recognized.

After the new PSW key has been placed in the PSW, bits 32-47 of general register  $R_1$  are ANDed with the PKM in control register 3, and the result replaces the PKM in control register 3.

The problem-state bit in the PSW is set to one.

In the 24-bit or 31-bit addressing mode, bit 32 of general register  $R_2$  is placed in bit position 32 of the PSW

as the new basic-addressing-mode bit. A branch address is generated from bits 33-63 of general register  $R_2$  under the control of the new basic addressing mode, and the result is placed in bit positions 64-127 of the PSW as the new instruction address.

In the 64-bit addressing mode, a branch address is generated from bits 0-63 of general register  $R_2$  and is placed in bit positions 64-127 of the PSW as the new instruction address. Bit 32 of the PSW remains unchanged.

Bits 48-55 and 60-63 of general register  $R_1$  may be used for future extensions and should be zeros; otherwise, the program may not operate compatibly in the future.

#### Reduced-Authority Operation

When BRANCH AND SET AUTHORITY is executed in the reduced-authority state, as indicated by the reduced-authority (RA) bit in the DUCT being one,  $R_2$  must be zero; otherwise, a special-operation exception is recognized.  $R_1$  may be zero or nonzero. The initial contents of general registers  $R_1$  and  $R_2$  are ignored.

If  $R_1$  is nonzero in the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are placed in bit positions 32 and 33-63, respectively, of general register  $R_1$ , and bits 0-31 of the register remain unchanged. If  $R_1$  is nonzero in the 64-bit addressing mode, bits 64-127 of the current PSW are placed in bit positions 0-63 of general register  $R_1$ . If  $R_1$  is zero, general register 0 remains unchanged.

In the 24-bit or 31-bit addressing mode, bit 0 of word 9 of the DUCT is placed in PSW bit position 32, and bits 1-31 of word 9, with 33 leftmost zeros appended, are placed in PSW bit positions 64-127.

In the 64-bit addressing mode, the contents of words 8 and 9 of the DUCT are placed in PSW bit positions 64-127, and bit 32 of the PSW remains unchanged.

In any addressing mode, the PKM, the PSW key, and the problem-state bit are restored from the DUCT, and the RA bit is set to zero, as previously described. There is no test for whether the restored PSW key is authorized by the restored PKM.

## Special Conditions

$R_2$  must be nonzero in the base-authority state and zero in the reduced-authority state. If either of these rules is violated, a special-operation exception is recognized, and the operation is suppressed.

In the problem state, the execution of the instruction in the base-authority state is subject to control by the PSW-key mask in control register 3. When the bit in the PSW-key mask corresponding to the PSW-key value to be set is one, the instruction is executed successfully. When the selected bit in the PSW-key mask is zero, a privileged-operation exception is recognized. In the supervisor state, any value for the PSW key is valid.

Key-controlled protection does not apply to any access made during the operation. Low-address protection does apply.

In the 24-bit or 31-bit addressing mode, the contents of word 9 of the DUCT are not checked for validity before they are loaded into the PSW. However, after loading, a specification exception is recognized, and a program interruption occurs, when the newly loaded PSW contains a zero in bit position 32 and the contents of bit positions 97-103 are not all zeros.

In this case, the operation is completed, and the resulting instruction-length code is 0. The specification exception, which in this case is listed as a program exception in this instruction, is described in “Early Exception Recognition” on page 6-8. It may be considered as occurring early in the process of preparing to execute the following instruction.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-2 on page 10-9.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Addressing (dispatchable-unit control table)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state, base-authority operation only)
- Protection (low-address; dispatchable-unit control table)
- Special operation
- Specification
- Trace

- |       |   |
|-------|---|
| 1.-6. | Exceptions with the same priority as the priority of program-interruption conditions for the general case.                                |
| 7.    | Access exceptions for second instruction halfword.  |
| 8.A   | Trace exceptions.   |
| 8.B   | Protection exception (low-address protection) for access to dispatchable-unit control table.  |
| 8.C.1 | Addressing exception for access to dispatchable-unit control table.   |
| 8.C.2 | Special-operation exception due to $R_2$ being zero in the base-authority state or $R_2$ being nonzero in the reduced-authority state.    |
| 8.C.3 | Privileged-operation exception due to selected PSW-key-mask bit being zero (base-authority operation only).                               |
| 9.    | Specification exception due to bit 32 of the newly loaded PSW zero when bits 97-103 are not all zeros (reduced-authority operation only). |

Figure 10-2. Priority of Execution: BRANCH AND SET AUTHORITY

### Programming Notes:

1. BRANCH AND SET AUTHORITY can improve performance by replacing to-current-primary forms of PROGRAM TRANSFER (PT-cp) and basic (nonstacking) PROGRAM CALL (PC-cp) instructions. PT-cp and PC-cp are often used

(within a single address space) to reduce the authority of the PSW-key mask (PKM) or change from supervisor state to problem state during a calling linkage made by PT-cp and then to restore the PKM authority or supervisor state during a return linkage made by PC-cp. Also, the PSW-key-setting operations of BRANCH AND

- SET AUTHORITY can be substituted for SET PSW KEY FROM ADDRESS instructions, and, since BRANCH AND SET AUTHORITY combines branching with PSW-key setting, it can be used to change the PSW key when branching from or to a fetch-protected program.
2. Only one base-authority state and one reduced-authority state are available to a dispatchable unit. Nested use of BRANCH AND SET AUTHORITY, that is, use within different subroutine levels, is not possible. The requirement that  $R_2$  must be nonzero in the base-authority state and zero in the reduced-authority state provides detection of an attempt to use BRANCH AND SET AUTHORITY in the base-authority state when the dispatchable unit is already in the reduced-authority state because of a previous use of the instruction in the base-authority state.
  3. BRANCH AND SET AUTHORITY in the base authority-state does not save an indication in the DUCT of whether the current addressing mode is the extended (64-bit) addressing mode or a basic (24-bit or 31-bit) addressing mode. The instruction, in either the base-authority state or the reduced-authority state, does not cause a switch between the extended addressing mode and a basic addressing mode. In the reduced-authority state, the contents of words 8 and 9 of the DUCT are interpreted based only on the current addressing mode. If saving occurs in the 31-bit addressing mode and then restoring occurs in the 64-bit addressing mode, bit 0 of word 9 of the DUCT will be used as an address bit instead of as the basic-addressing-mode bit. If saving occurs in the 64-bit addressing mode and then restoring occurs in the 24-bit addressing mode, an early specification exception may be recognized, after the instruction execution is completed, because bits 97-103 of the PSW may be nonzero when bit 32 is zero.
  4. The instruction may be referred to as BSA-ba or BSA-ra depending on whether it is executed in the base-authority state or the reduced-authority state, respectively.

## BRANCH AND STACK

BAKR	$R_1, R_2$	[RRE]
'B240'		$R_1 \quad R_2$

0                  16                24                28                31

A linkage-stack branch state entry is formed, and the current PSW, except with an unpredictable PER mask and with the addressing-mode bits and instruction address replaced from the first operand, is placed in the state entry. Subsequently, the updated instruction address in the current PSW is replaced from the second operand. Indications of the current addressing-mode bits and the new instruction address are placed in the state entry, and the PSW-key mask, PASN, SASN, EAX, and contents of general registers 0-15 and access registers 0-15 also are placed in the state entry. When the ASN-and-LX-reuse facility is installed and the ASN-and-LX-reuse control in control register 0 is one, the PASTEIN and SASTEIN also are placed in the state entry. The action associated with an operand is not performed if the  $R$  field designating the operand is zero.

When the  $R_1$  field is nonzero, the contents of general register  $R_1$  specify an address referred to as the return address.

When  $R_1$  is nonzero and bit 63 of general register  $R_1$  is zero, the return address is generated from the contents of the register under the control of the basic addressing mode specified by bit 32 of the register: 24-bit mode if bit 32 is zero, or 31-bit mode if bit 32 is one. Bit 32 of the register and the return address are substituted for the basic-addressing-mode bit, bit 32, and the updated instruction address, respectively, in the current PSW when the contents of that PSW are placed in the state entry. The extended-addressing-mode bit, bit 31, is set to zero in the PSW that is placed in the state entry. The contents of the current PSW are not changed.

When  $R_1$  is nonzero and bit 63 of general register  $R_1$  is one, the return address is generated from the contents of the register under the control of the 64-bit addressing mode. Bits 0-62 of the return address, with a zero appended on the right, are substituted for the updated instruction address in the current PSW when the contents of that PSW are placed in the state entry. Bits 31 and 32 are set to one in the PSW that is placed in the state entry. The contents of the current PSW are not changed.

When the  $R_1$  field is zero, the current PSW is placed in the state entry without any change except for an unpredictable PER mask.

Subsequently, when the  $R_2$  field is nonzero, the instruction address in the current PSW is replaced by the branch address. The branch address is gener-

ated from the contents of general register R<sub>2</sub> under the control of the current addressing mode. When the R<sub>2</sub> field is zero, the operation is performed without branching.

The branch state entry is formed and information is placed in it as described in “Stacking Process” on page 5-80.

In the 24-bit or 31-bit addressing mode, bits 33-63 of the branch address (or of the updated instruction address if the operation is performed without branching) are placed in bit positions 33-63 of bytes 144-151 in the state entry, bit 32 of the current PSW is placed in bit position 32 of those bytes, and zeros are placed in bit positions 0-31 of the bytes.

In the 64-bit addressing mode, bits 0-62 of the branch address (or of the updated instruction address if the operation is performed without branching) are placed in bit positions 0-62 of bytes 144-151 in the state entry, and a one is placed in bit position 63 of those bytes.

The entry-type code in the state entry is 0001100 binary.

Key-controlled protection does not apply to accesses to the linkage stack, but low-address and DAT protection do apply.

### Special Conditions

The CPU must be in the primary-space mode or access-register mode; otherwise, a special-operation exception is recognized.

A stack-full or stack-specification exception may be recognized during the stacking process.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-3 on page 10-11.

- |       |  |
|-------|--|
| 1.-6. | Exceptions with the same priority as the priority of program-interruption conditions for the general case.   |
| 7.A   | Access exceptions for second instruction halfword.   |
| 7.B   | Special-operation exception due to DAT being off or the CPU being in secondary-space mode or home-space mode.  |
| 8.A   | Trace exceptions (only if R <sub>2</sub> is nonzero).  |
| 8.B.1 | Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.<br><br><b>Note:</b> Exceptions 8.B.2-8.B.7 can occur only if there is not enough remaining free space in the current linkage-stack section. |
| 8.B.2 | Stack-specification exception due to remaining-free-space value in current linkage-stack entry not being a multiple of 8.  |
| 8.B.3 | Access exceptions (fetch) for second word of the trailer entry of the current section. The entry is presumed to be a trailer entry; its entry-type field is not examined.  |
| 8.B.4 | Stack-full exception due to forward-section validity bit in the trailer entry being zero.  |
| 8.B.5 | Access exceptions (fetch) for entry descriptor of the header entry of the next section. This entry is presumed to be a header entry; its entry-type field is not examined.   |
| 8.B.6 | Stack-specification exception due to not enough remaining free space in the next section.  |
| 8.B.7 | Access exceptions (store) for second word of the header entry of the next section. If there is no exception, the header is now called the current entry.   |
| 8.B.8 | Access exceptions (store) for entry descriptor of the current entry and for the new state entry.   |

Figure 10-3. Priority of Execution: BRANCH AND STACK

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch or store, except for key-controlled protection, linkage-stack entry)
- Special operation
- Stack full
- Stack specification
- Trace

**Programming Notes:**

1. Examples of the use of the BRANCH AND STACK instruction are given in Appendix A, "Number Representation and Instruction-Use Examples."
2. In no case does BRANCH AND STACK change the current addressing mode.
3. The effect when the R<sub>1</sub> field is zero is that the return address, which would otherwise be specified by the R<sub>1</sub> general register, is the address of the next sequential instruction. In this case, BRANCH AND STACK provides a program-linkage function that is comparable to the function of BRANCH AND SAVE.
4. BRANCH AND STACK with a nonzero R<sub>1</sub> field is intended for use at or near the entry point of a called program. The program may be called by means of BRANCH AND LINK (BALR) or BRANCH AND SAVE (BAS or BASR) from a program being executed in the 24-bit or 31-bit addressing mode, by means of BRANCH AND SAVE AND SET MODE from a program being executed in any addressing mode, or by means of a BRANCH AND SET MODE instruction located in a "glue module" and being executed in any addressing mode. In all of these cases when the nonzero R<sub>1</sub> field of the calling instruction is the same as the R<sub>1</sub> field of BRANCH AND STACK, and even when the addressing mode was changed during the calling linkage, BRANCH AND STACK correctly saves the addressing mode and return address of the calling program so that the subsequent execution of PROGRAM RETURN will return correctly to the calling program.

**BRANCH IN SUBSPACE GROUP**

BSG	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
0	'B258' //////////////// R <sub>1</sub> R <sub>2</sub>	16 24 28 31

Provided that the current primary address space is in the subspace group, if any, associated with the current dispatchable unit, the access-list-entry token (ALET) in access register R<sub>2</sub> is translated by means of a special form of access-register translation (ART) to locate a destination ASN-second-table entry (DASTE). If the DASTE specifies the base space of the subspace group, the primary ASCE (PASCE) in control register 1 is replaced by the ASCE in the DASTE. If the DASTE specifies a subspace of the group, bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the DASTE. In either case, the following actions also occur.

In the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are saved in bit positions 32 and 33-63, respectively, of general register R<sub>1</sub>, and bits 0-31 of the register remain unchanged. Subsequently, the basic-addressing-mode bit and bits 33-63 of the instruction address in the current PSW are replaced from bit positions 32-63 of general register R<sub>2</sub>, and bits 0-31 of the register are ignored.

In the 64-bit addressing mode, bits 64-127 of the current PSW, the updated instruction address, are saved in bit positions 0-63 of general register R<sub>1</sub>. Subsequently, the instruction address in the current PSW is replaced from bit positions 0-63 of general register R<sub>2</sub>. Bit 32 of the PSW remains unchanged.

In any addressing mode, general register 0 remains unchanged if the R<sub>1</sub> field is zero.

The secondary ASCE (SASCE) in control register 7 is set equal to the new PASCE in control register 1. Also, the secondary ASN (SASN), bits 48-63 of control register 3, is set equal to the primary ASN (PASN), bits 48-63 of control register 4. If the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0, the secondary ASTEIN (SASTEIN), bits 0-31 of control register 3, is set equal to the primary ASTEIN (PASTEIN), bits 0-31 of control register 4.

The current primary address space is in the subspace group for the dispatchable unit if the current primary-ASTE origin (PASTEO), bits 33-57 of control register 5, designates the ASTE for the base space of the group. The PASTEO designates the base-space ASTE if the PASTEO is equal to the base-ASTE origin (BASTEO), bits 1-25 of word 0 of the dispatchable-unit control table (DUCT). For determining whether the PASTEO equals the BASTEO, either the PASTEO may be compared to the BASTEO or the entire contents of bit positions 32-63 of control register 5 may be compared to the entire contents of word 0 of the DUCT.

Ordinary ART is described in “Access-Register-Translation Process” on page 5-55. The special ART performed by this instruction is contrasted to ordinary ART as follows:

1. The special ART is performed regardless of whether the CPU is in the access-register mode.
2. If the ALET being translated is 00000000 hex, called ALET 0, the DASTE is the ASTE for the base space. Bit 0 of the DASTE is ignored.
3. If the ALET is 00000001 hex, called ALET 1, the DASTE is the ASTE for the last subspace entered by the dispatchable unit by means of BRANCH IN SUBSPACE GROUP. That ASTE is designated by the subspace-ASTE origin (SSASTEO), bits 1-25 of word 1 of the DUCT. A special-operation exception is recognized if a subspace has not previously been entered, as indicated by an SSASTEO of all zeros. An ASTE-validity exception is recognized if bit 0 of the DASTE is one. An ASTE-sequence exception is recognized if the ASTE sequence number (ASTESN) in the DASTE does not equal the subspace ASTESN (SSASTESN) in word 3 of the DUCT. The DASTE located because of ALET 1 is considered to specify a subspace even if, due to an error, the DASTE is the ASTE for the base space. That is, there is no comparison of the SSASTEO to the BASTEO.
4. If the ALET is other than ALET 0 and ALET 1, an ASTE is located by obtaining its origin from an access-list entry (ALE) in a way similar to ordinary ART, and the DASTE is that located ASTE. In this case, as in ordinary ART:
  - An ALET-specification exception is recognized if bits 0-6 of the ALET are not zeros.

- An ALEN-translation exception is recognized if the ALE is outside the effective access list or bit 0 of the ALE is one.
- An ASTE-validity exception is recognized if bit 0 of the DASTE is one.
- An ASTE-sequence exception is recognized if the ASTE sequence number (ASTESN) in the DASTE does not equal the ASTESN in the ALE.

The operation differs from ordinary ART in that the ALE sequence number (ALESN) in the ALE is not compared to the ALESN in the ALET, and the private bit in the ALE is treated as zero. Thus, ALE-sequence and extended-authority exceptions cannot occur.

The fetch-only bit in the ALE is ignored.

When the ALET is other than ALET 0 and ALET 1, the special ART may be performed by using the ART-lookaside buffer (ALB).

The DASTE located due to an ALET other than ALET 0 and ALET 1 may be the ASTE for the base space of the subspace group associated with the dispatchable unit. The DASTE is the base-space ASTE if the DASTE origin (DASTEO) obtained from an ALE by ART equals the BASTEO in the DUCT. For determining whether the DASTEO equals the BASTEO, either the DASTEO may be compared to the BASTEO, or the DASTEO with one leftmost and six rightmost zeros appended may be compared to the entire contents of word 0 of the DUCT. If the DASTE is not the base-space ASTE, the DASTE is treated as the ASTE for a subspace of the dispatchable unit’s subspace group provided that (1) the subspace-group bit, bit 54, in the ASCE in the DASTE is one, and (2) the DASTE does not specify the base space of another subspace group. The DASTE specifies the base space of another subspace group if the base-space bit, bit 31 of word 0 of the DASTE, is one. A special-operation exception is recognized if either of those two provisions is not met.

If the DASTE specifies the base space of the subspace group, the PASCE in control register 1 is replaced by the ASCE in the DASTE. If the DASTE specifies a subspace, bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the DASTE, and bits 56 and 57 of the PASCE, the storage-alteration-event bit and space-switch-event-control bit, remain unchanged.

If  $R_1$  is nonzero in the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are placed in bit positions 32 and 33-63, respectively, of general register  $R_1$ , and bits 0-31 of the register remain unchanged. If  $R_1$  is nonzero in the 64-bit addressing mode, bits 64-127 of the current PSW, the updated instruction address, are placed in bit positions 0-63 of general register  $R_1$ . If  $R_1$  is zero, general register 0 remains unchanged.

Whether  $R_2$  is nonzero or zero, in the 24-bit or 31-bit addressing mode, bits 32-63 of general register  $R_2$  specify the new basic addressing mode and designate the branch address. Bit 32 of the register specifies the new basic addressing mode and replaces bit 32 of the current PSW, and the branch address is generated from the contents of bit positions 33-63 of the register under the control of the new basic addressing mode.

When  $R_2$  is nonzero or zero in the 64-bit addressing mode, the contents of general register  $R_2$  designate the branch address. The branch address is generated from the contents of the register under the control of the 64-bit addressing mode. Bit 32 of the PSW remains unchanged.

Regardless of the addressing mode, the new value for the PSW is computed before general register  $R_1$  is changed.

The secondary ASCE (SASCE) in control register 7 is set equal to the new PASCE in control register 1. The secondary ASN (SASN), bits 48-63 of control register 3, is set equal to the primary ASN (PASN), bits 48-63 of control register 4. If the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the secondary ASTEIN (SASTEIN), bits 0-31 of control register 3, is set equal to the primary ASTEIN (PASTEIN), bits 0-31 of control register 4.

If the DASTE specifies the base space, the subspace-active bit, bit 0 of word 1 of the DUCT, is set to zero, and bits 1-31 of word 1 remain unchanged. If the DASTE specifies a subspace by means of ALET 1, then (1) the subspace-active bit is set to one, (2) the SSASTEO in bit positions 1-25 of word 1 remains unchanged, and (3) bits 26-31 of word 1 either are set to zeros or remain unchanged. If the DASTE specifies a subspace by means of an ALET

other than ALET 1, then (1) the subspace-active bit is set to one, (2) the DASTEO is stored in bit positions 1-25 of word 1 as the SSASTEO, (3) zeros are stored in bit positions 26-31 of word 1, and (4) the ASTESN in the DASTE is stored in word 3 of the DUCT as the SSATESN.

The fetch, store, and update references to the DUCT are single-access references and appear to be word concurrent as observed by other CPUs. The words of the DUCT are accessed in no particular order.

The operation, since it changes a translation parameter in control register 1, causes all copies of prefetched instructions to be discarded, except when in the home-space mode.

### **Special Conditions**

DAT must be on; otherwise, a special-operation exception is recognized. A special-operation exception is also recognized if the current primary address space is not in a subspace group associated with the current dispatchable unit, if the ALET in access register  $R_2$  is ALET 1 but a subspace has not previously been entered by the dispatchable unit by means of BRANCH IN SUBSPACE GROUP, or if the ALET used is other than ALET 0 and ALET 1 and the destination ASTE does not specify the base space or a subspace of the subspace group.

The primary space-switch-event-control bit, bit 57 of control register 1 either before or after the operation, does not cause a space-switch-event program interruption to occur.

Key-controlled protection does not apply to any access made during the operation. Low-address protection does apply.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in the figure "Priority of Execution: BRANCH IN SUBSPACE GROUP."

**Condition Code:** The code remains unchanged.

### **Program Exceptions:**

- Addressing (dispatchable-unit control table, effective access-list designation, access-list entry, destination ASN-second-table entry)

- ALET specification
- ALEN translation
- ASTE sequence
- ASTE validity
- Protection (low-address; dispatchable-unit control table)
- Special operation
- Trace

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off.
8.A	Trace exceptions.
8.B	Protection exception (low-address protection) for access to dispatchable-unit control table.
8.C.1	Addressing exception for access to dispatchable-unit control table.
8.C.2	Special-operation exception due to current primary address space not being in a subspace group associated with the current dispatchable unit (primary-ASTE origin in control register 5 not equal to base-ASTE origin in dispatchable-unit control table).
	<b>Note:</b> Exception 8.C.3.A can occur only if the access-list-entry token (ALET) in access register R <sub>2</sub> is ALET 0.
8.C.3.A	Addressing exception for access to base ASTE (ASTE designated by base-ASTE origin in dispatchable-unit control table).
	<b>Note:</b> Exceptions 8.C.3.B.1-8.C.3.B.4 can occur only if the access-list-entry token (ALET) in access register R <sub>2</sub> is ALET 1.
8.C.3.B.1	Special-operation exception due to subspace-ASTE origin in dispatchable-unit control table being zero.
8.C.3.B.2	Addressing exception for access to subspace ASTE.
8.C.3.B.3	ASTE-validity exception due to bit 0 in subspace ASTE being one.
8.C.3.B.4	ASTE-sequence exception due to ASTE sequence number in subspace ASTE not being equal to subspace-ASTE sequence number in dispatchable-unit control table.
	<b>Note:</b> Exceptions 8.C.3.C.1-8.C.3.C.9 can occur only if the access-list-entry token (ALET) in access register R <sub>2</sub> is other than ALET 0 and ALET 1.
8.C.3.C.1	ALET-specification exception due to bits 0-6 of ALET not being all zeros.
8.C.3.C.2	Addressing exception for access to effective access-list designation.
8.C.3.C.3	ALEN-translation exception due to access-list entry being outside the list.
8.C.3.C.4	Addressing exception for access to access-list entry.
8.C.3.C.5	ALEN-translation exception due to I bit in access-list entry being one.
8.C.3.C.6	Addressing exception for access to destination ASTE.
8.C.3.C.7	ASTE-validity exception due to bit 0 in destination ASTE being one.
8.C.3.C.8	ASTE-sequence exception due to ASTE sequence number (ASTESN) in access-list entry not being equal to ASTESN in destination ASTE.
8.C.3.C.9	Special-operation exception due to destination-ASTE origin not equal to base-ASTE origin in dispatchable-unit control table and (1) subspace-group bit, bit 54 in address-space-control element in destination ASTE being zero or (2) base-space bit 31, in destination ASTE being one.

Figure 10-4. Priority of Execution: BRANCH IN SUBSPACE GROUP

**Programming Notes:**

1. See the discussion of BRANCH IN SUBSPACE GROUP in "Subroutine Linkage without the Linkage Stack" on page 5-11. It is intended that there be a separate ASN-second-table entry (ASTE) for each of the base space and each subspace of a subspace group. The ASTEs for the subspaces can be "pseudo" ASTEs as described in the programming note in "Address-Space Number" on page 3-19. A subspace can contain a subset of the storage in the base space by having the DAT tables for the subspace designate a subset of the pages that are designated by the DAT tables for the base space. A dispatchable unit has access to a subspace if an access-list entry designating the ASTE for the subspace is in the primary-space or dispatchable-unit access list of the dispatchable unit.
2. BRANCH IN SUBSPACE GROUP can be used to give control from the base space to a subspace, from a subspace to another subspace, and from a subspace to the base space. The instruction can also be used to give control from the base space to the base space or from a subspace to the same subspace.
3. Since BRANCH IN SUBSPACE GROUP sets the secondary address-space-control element (ASCE) in control register 7 equal to the new primary ASCE in control register 1 (along with setting the secondary ASN in control register 3 equal to the primary ASN in control register 4), the program in an address space given control by BRANCH IN SUBSPACE GROUP does not have access to the calling program's address space by means of that address space being the secondary address space.
4. When a dispatchable unit has used BRANCH IN SUBSPACE GROUP to enter a subspace and has not subsequently used BRANCH IN SUBSPACE GROUP to return to the base space, the dispatchable unit is said to be "subspace active." When LOAD ADDRESS SPACE PARAMETERS, PROGRAM CALL, PROGRAM RETURN, PROGRAM TRANSFER, PROGRAM TRANSFER WITH INSTANCE, SET SECONDARY ASN, or SET SECONDARY ASN WITH INSTANCE places an ASCE in control register 1 as the primary ASCE or in control register 7 as the secondary ASCE, and if (1) the ASCE has the subspace-group bit on in it, (2) the dispatchable

unit is subspace active, and (3) the ASCE was obtained from the ASN-second-table entry (ASTE) for the base space of the current dispatchable unit, then the instruction (any of the seven named instructions) replaces bits 0-55 and 58-63 of the ASCE in the control register with the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details about the effects of the subspace-group facility on the seven named instructions are given in "Subspace-Replacement Operations" on page 5-66 and in the definitions of the instructions.

5. The use of BRANCH IN SUBSPACE GROUP (BSG) along with PROGRAM CALL (PC) and either PROGRAM TRANSFER (PT) (or PROGRAM TRANSFER WITH INSTANCE) or PROGRAM RETURN (PR) can produce results that may be unexpected. Consider the following sequence of operations:
  - a. Start in the base space
  - b. BSG to a subspace
  - c. PC (the first PC) to an address space that is not in the subspace group.
  - d. PC (the second PC) to the base space. Since the dispatchable unit is subspace active, control is given to the subspace.
  - e. BSG back to the base space.
  - f. PT or PR (paired with the second PC) back to the address space that is not in the subspace group.
  - g. PT or PR (paired with the first PC) back to the subspace group. Since the dispatchable unit is no longer subspace active, control is given to the base space even though the first PC was issued in the subspace.
6. BRANCH IN SUBSPACE GROUP does not perform the serialization or checkpoint-synchronization functions, but it does cause all copies of prefetched instructions to be discarded except when in the home-space mode.
7. When the R<sub>2</sub> field designates access register 0, the access register is treated as containing ALET 0 regardless of the contents of the access register.

## COMPARE AND SWAP AND PURGE

CSP	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
0	'B250'	R <sub>1</sub> R <sub>2</sub>

16      24      28      31

CSPG	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
0	'B98A'	R <sub>1</sub> R <sub>2</sub>

16      24      28      31

The first and second operands are compared. If they are equal, contents of general register R<sub>1</sub> + 1 are stored at the second-operand location, and a purging operation is performed. If they are unequal, the second operand is loaded at the first-operand location. The result of the comparison is indicated in the condition code.

For COMPARE AND SWAP AND PURGE (CSP), the first operand is the contents of bit positions 32-63 of general register R<sub>1</sub>. The second operand is a word in storage.

For COMPARE AND SWAP AND PURGE (CSPG), the first operand is the contents of bit positions 0-63 of general register R<sub>1</sub>. The second operand is a doubleword in storage.

For both CSP and CSPG, the location of the leftmost byte of the second operand is designated by contents of general register R<sub>2</sub>.

The purging operation applies to ART-lookaside buffers (ALBs) and translation-lookaside buffers (TLBs) in all CPUs in the configuration. Either ALBs or TLBs, or both ALBs and TLBs, may be selected for purging. All entries are cleared from the selected buffers.

The purging operation is specified by means of bits 62 and 63 of general register R<sub>2</sub>. When bit 62 is one, entries are cleared from ALBs. When bit 63 is one, entries are cleared from TLBs. When bits 62 and 63 both are ones, entries are cleared from ALBs and TLBs. When bits 62 and 63 both are zeros, no entries are cleared.

The handling of the address in general register R<sub>2</sub> is dependent on the addressing mode. For CSP in the 24-bit addressing mode, the contents of bit positions 40-61 of general register R<sub>2</sub>, with two zeros

appended on the right, constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-61 of the register, with two zeros appended on the right, constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-61 of the register, with two zeros appended on the right, constitute the address.

For CSPG in the 24-bit addressing mode, the contents of bit positions 40-60 of general register R<sub>2</sub>, with three zeros appended on the right, constitute the address, and the contents of bit positions 0-39 and 61 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-60 of the register, with three zeros appended on the right, constitute the address, and the contents of bit positions 0-32 and 61 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-60 of the register, with three zeros appended on the right, constitute the address, and the contents of bit position 61 are ignored.

The contents of the registers just described are shown in Figure 10-5 on page 10-18 and Figure 10-6 on page 10-18. When an equal comparison occurs, the contents of bit positions 32-63 of general register R<sub>1</sub> + 1 for CSP, or of bit positions 0-63 for CSPG, are stored at the second-operand location. The fetch of the second operand for purposes of comparison and the store into the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs.

When the result of the comparison is unequal, the second-operand is loaded at the first-operand location, bits 0-31 of general register R<sub>1</sub> remain unchanged for CSP only, and the second-operand location remains unchanged. However, on some models, the second operand may be fetched and subsequently stored back unchanged at the second-operand location. This update appears to be a block-concurrent interlocked-update reference as observed by other CPUs.

A serialization function is performed before the operand is fetched and again after the operation is completed.

When an equal comparison occurs, this CPU clears entries from its ALB and TLB, as specified by bits 62 and 63 of general register R<sub>2</sub>, and signals all CPUs in the configuration to clear the same specified entries

*Figure 10-5. Register Contents for COMPARE AND SWAP AND PURGE (CSP)*

$R_1$	First Operand	0	63
$R_1 + 1$	Swap Value	0	63
<u>24-Bit Addressing Mode</u>			
$R_2$	Second-Operand Address	0	40 61 62 63
<u>31-Bit Addressing Mode</u>			
$R_2$	Second-Operand Address	0	33 61 62 63
<u>64-Bit Addressing Mode</u>			
$R_2$	Second-Operand Address	0	61 62 63

Figure 10-6. Register Contents for COMPARE AND SWAP AND PURGE (CSPG)

from their ALBs and TLBs. The ALB entries that are cleared are all ALB access-list designations, access-list entries, ASN-second-table entries, and authority-table entries. The TLB entries that are cleared are all combined region-and-segment-table entries, page-table entries, and real-space entries.

The execution of COMPARE AND SWAP AND PURGE is not completed on the CPU which executes it until (1) all specified entries have been cleared from the ALB and TLB of this CPU and (2) all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits, by using the specified ALB and TLB entries.

### **Special Conditions**

The  $R_1$  field must designate an even register; otherwise, a specification exception is recognized.

### ***Resulting Condition Code:***

- 0 First and second operands equal, second operand replaced by contents of general register  $R_1 + 1$
  - 1 First and second operands unequal, first operand replaced by second operand
  - 2 --
  - 3 --

## ***Program Exceptions:***

- Access (fetch and store, operand 2)
  - Operation (if DAT-enhancement facility is not installed, CSPG only)
  - Privileged operation
  - Specification

**Programming Note:** COMPARE AND SWAP AND PURGE provides a broadcast form of the PURGE ALB and PURGE TLB instructions, thus making it possible to avoid uses of SIGNAL PROCESSOR.

## DIAGNOSE

'83'	
0	8

The CPU performs built-in diagnostic functions, or other model-dependent functions. The purpose of the diagnostic functions is to verify proper functioning of equipment and to locate faulty components. Other model-dependent functions may include disabling of failing buffers, reconfiguration of CPUs, storage, and channel paths, and modification of control storage.

Bits 8-31 may be used as in the SI or RS formats, or in some other way, to specify the particular diagnostic function. The use depends on the model.

The execution of the instruction may affect the state of the CPU and the contents of a register or storage location, as well as the progress of an I/O operation. Some diagnostic functions may cause the test indicator to be turned on.

**Resulting Condition Code:** The code is unpredictable.

## ***Program Exceptions:***

- Privileged operation
  - Depending on the model, other exceptions may be recognized.

## Programming Notes:

1. Since the instruction is not intended for problem-state-program or control-program use, DIAGNOSE has no mnemonic.

2. DIAGNOSE, unlike other instructions, does not follow the rule that programming errors are distinguished from equipment errors. Improper use of DIAGNOSE may result in false machine-check indications or may cause actual machine malfunctions to be ignored. It may also alter other aspects of system operation, including instruction execution and channel-program operation, to an extent that the operation does not comply with that specified in this publication. As a result of the improper use of DIAGNOSE, the system may be left in such a condition that the power-on reset or initial-microprogram-loading (IML) function must be performed. Since the function performed by DIAGNOSE may differ from model to model and between versions of a model, the program should avoid issuing DIAGNOSE unless the program recognizes both the model number and version code stored by STORE CPU ID.

# **EXTRACT AND SET EXTENDED AUTHORITY**

ESEA	R <sub>1</sub>	[RRE]
'B99D'		R <sub>1</sub>
0	16	24 28 31

The extended authorization index (EAX), bits 32-47 of control register 8, is saved in bit positions 32-47 of the first operand, and then the EAX in control register 8 is replaced by the contents of bit positions 48-63 of the first operand. Bits 0-31 of the first operand are ignored, and bits 0-31 and 48-63 of the operand remain unchanged.

**Condition Code:** The code remains unchanged.

## ***Program Exceptions:***

- Privileged operation

## **EXTRACT PRIMARY ASN**

EPAR	R <sub>1</sub>	[RRE]
'B226'	/ / / / / /	R <sub>1</sub> / / /

## EXTRACT PRIMARY ASN AND INSTANCE

EPAIR	R <sub>1</sub>	[RRE]
'B99A'	R <sub>1</sub>	0 16 24 28 31

The 16-bit PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of general register R<sub>1</sub>. Bits 32-47 of the general register are set to zeros.

In the EXTRACT PRIMARY ASN AND INSTANCE operation, the PASTEIN, bits 0-31 of control register 4, is placed in bit positions 0-31 of general register R<sub>1</sub>. In the EXTRACT PRIMARY ASN operation, bits 0-31 of general register R<sub>1</sub> remain unchanged.

### Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-7.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Operation (if the ASN-and-LX-reuse facility is not installed, EPAIR only)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation

- |       |  |
|-------|--|
| 1.-6. | Exceptions with the same priority as the priority of program-interruption conditions for the general case.                     |
| 7.A   | Access exceptions for second instruction halfword.   |
| 7.B.1 | Operation exception if the ASN-and-LX-reuse facility is not installed (EPAIR only).  |
| 7.B.2 | Special-operation exception due to DAT being off.  |
| 8.    | Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state. |

Figure 10-7. Priority of Execution: EXTRACT PRIMARY ASN

## EXTRACT SECONDARY ASN

ESAR	R <sub>1</sub>	[RRE]
'B227'	R <sub>1</sub>	0 16 24 28 31

## EXTRACT SECONDARY ASN AND INSTANCE

ESAIR	R <sub>1</sub>	[RRE]
'B99B'	R <sub>1</sub>	0 16 24 28 31

The 16-bit SASN, bits 48-63 of control register 3, is placed in bit positions 48-63 of general register R<sub>1</sub>. Bits 32-47 of the general register are set to zeros.

In the EXTRACT SECONDARY ASN AND INSTANCE operation, the SASTEIN, bits 0-31 of control register 3, is placed in bit positions 0-31 of general register R<sub>1</sub>. In the EXTRACT SECONDARY ASN operation, bits 0-31 of general register R<sub>1</sub> remain unchanged.

### Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the

supervisor state, the extraction-authority-control bit is not examined.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-8 on page 10-21.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Operation (if the ASN-and-LX-reuse facility is not installed, ESAIR only)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation

1..6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B.1	Operation exception if the ASN-and-LX-reuse facility is not installed (ESAIR only).
7.B.2	Special-operation exception due to DAT being off.
8.	Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state.

Figure 10-8. Priority of Execution: EXTRACT SECONDARY ASN

## EXTRACT STACKED REGISTERS

EREG	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
0	'B249'   / / / / /   R <sub>1</sub>   R <sub>2</sub>	16 24 28 31

EREGG	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
0	'B90E'   / / / / /   R <sub>1</sub>   R <sub>2</sub>	16 24 28 31

Contents of a set of general registers and a set of access registers that were saved in the last state entry in the linkage stack are restored to the registers. Each set of registers begins with register R<sub>1</sub> and ends with register R<sub>2</sub>.

For EXTRACT STACKED REGISTERS (EREG), the contents of bit positions 32-63 of the general registers are restored, and the contents of bit positions 0-31 of the registers remain unchanged. For EXTRACT STACKED REGISTERS (EREGG), the contents of bit positions 0-63 of the general registers are restored. In either case, the contents of bit positions 0-31 of the access registers are restored.

For each of the general registers and the access registers, the registers are loaded in ascending order of their register numbers, starting with register R<sub>1</sub> and continuing up to and including register R<sub>2</sub>, with register 0 following register 15. The bit positions of each register are loaded from the position in the state entry where the contents of the bit positions were saved when the state entry was created. The contents of the state entry remain unchanged.

The last state entry is located as described in "Unstacking Process" on page 5-82. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

Key-controlled protection does not apply to references to the linkage stack.

#### Special Conditions

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-9 on page 10-22.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Access (fetch, except for protection, linkage-stack entry)
- Special operation
- Stack empty
- Stack specification

- Stack type

1.6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode.
8.	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.
9.	Stack-type exception due to current entry not being a state entry or header entry. <b>Note:</b> Exceptions 10-14 can occur only if the current entry is a header entry.
10.	Access exceptions (fetch) for second word of the header entry.
11.	Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.
12.	Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.
13.	Stack-specification exception due to preceding entry being a header entry.
14.	Stack-type exception due to preceding entry not being a state entry.
15.	Access exceptions (fetch) for the selected contents of the state entry.

Figure 10-9. Priority of Execution: EXTRACT STACKED REGISTERS

## EXTRACT STACKED STATE

ESTA	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B24A'		R <sub>1</sub> R <sub>2</sub>
0	16 24 28	31

Sixty-four or 128 bits of status information in the last state entry in the linkage stack are placed in the pair of general registers designated by the R<sub>1</sub> field. The condition code is set to indicate whether the state entry is a branch state entry or a program-call state entry.

The R<sub>1</sub> field designates the even-numbered register of an even-odd pair of general registers.

Bits 56-63 of general register R<sub>2</sub> are an unsigned binary integer that is used as a code to select the

state-entry byte positions, or byte and bit positions, from which information is to be extracted, as follows:

Code (Bits 56-63 of Gen. Reg. R <sub>2</sub> )	State-Entry Byte Positions, or Byte and Bit Positions, Selected
0	128-135
1	136-139, 140.0, and 168-175.33-63 (see text)
2	144-151
3	152-159
4	136-143 and 168-175
5	176-183

For a code of 0, 2, or 3 in bit positions 56-63 of general register R<sub>2</sub>, the contents of the leftmost four bytes of the eight bytes of status information are placed in bit positions 32-63 of general register R<sub>1</sub>, and the contents of the rightmost four bytes of the status information are placed in bit positions 32-63 of general register R<sub>1</sub> + 1. The contents of bit positions 0-31 of general registers R<sub>1</sub> and R<sub>1</sub> + 1 remain unchanged.

For a code of 1 in bit positions 56-63 of general register R<sub>2</sub>, the contents of bytes 136-139 of the state entry, which are bits 0-31 of the PSW in the state entry, are placed in bit positions 32-63 of general register R<sub>1</sub>; the contents of bit position 0 of byte 140 of the entry, which is bit 32 of that PSW, are placed in

bit position 32 of general register  $R_1 + 1$ ; and the contents of bit positions 33-63 of bytes 168-175 of the entry, which are bits 97-127 of the PSW, are placed in bit positions 33-63 of general register  $R_1 + 1$ . However, bit 44 of general register  $R_1$ , which corresponds to bit 12 of the PSW in the state entry, is set to one, indicating the ESA/390 mode. Also, if bits 0-32 of bytes 168-175 of the state entry are not all zeros, bit 63 of general register  $R_1 + 1$  is set to one; otherwise, bit 63 remains with the value loaded from bit position 63 of bytes 168-175 of the state entry. The contents of bit positions 0-31 of general registers  $R_1$  and  $R_1 + 1$  remain unchanged.

For a code of 4 in bit positions 56-63 of general register  $R_2$ , the contents of bytes 136-143 of the state entry, which are bits 0-63 of the PSW in the state entry, are placed in bit positions 0-63 of general register  $R_1$ , and the contents of bytes 168-175 of the state entry, which are bits 64-127 of that PSW, are placed in bit positions 0-63 of general register  $R_1 + 1$ .

Code 5 in bit positions 56-63 of general register  $R_2$  is valid only if the ASN-and-LX-reuse facility is installed. For code 5, the contents of the leftmost four bytes of the eight bytes of status information are placed in bit positions 0-31 of general register  $R_1$ , and the contents of the rightmost four bytes of the status information are placed in bit positions 0-31 of general register  $R_1 + 1$ . The contents of bit positions 32-63 of general registers  $R_1$  and  $R_1 + 1$  remain unchanged.

The format of byte positions 128-183 of the state entry is as follows:

PKM	SASN	EAX	PASN	
128	130	132	134	135
PSW Bits 0-63				
136				143

In a Branch State Entry Made in 24-Bit or 31-Bit Mode

A	Bits 33-63 of Branch Address	
144	148	151

In a Branch State Entry Made in 64-Bit Mode

Bits 0-62 of Branch Address	1
144	151

In a Program-Call State Entry Made When Resulting Mode Is 24 Bit or 31 Bit

The contents of the state entry remain unchanged.

The last state entry is located as described in “Unstacking Process” on page 5-82. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

When the entry-type code in the entry descriptor of the state entry is 0001100 binary, indicating a branch state entry, the condition code is set to 0. When the entry-type code is 0001101 binary, indicating a program-call state entry, the condition code is set to 1.

Key-controlled protection does not apply to references to the linkage stack.

Bits 0-55 of general register  $R_2$  are ignored.

### Special Conditions

A specification exception is recognized when  $R_1$  is odd or the code in bit positions 56-63 of general register  $R_2$  is greater than 4 when the ASN-and-LX-reuse facility is not installed or is greater than 5 when the facility is installed.

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-10 on page 10-24.

- 0 Branch state entry
- 1 Program-call state entry

| 1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.   |
| 7.A Access exceptions for second instruction halfword.   |
| 7.B Special-operation exception due to DAT being off or the CPU being in secondary-space mode.   |
| 8.A Specification exception due to $R_1$ being odd or bits 56-63 of general register $R_2$ having a value greater than 4 when the ASN-and-LX-reuse facility is not installed or greater than 5 when the facility is installed. |
| 8.B.1 Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.   |
| 8.B.2 Stack-type exception due to current entry not being a state entry or header entry.<br><br><b>Note:</b> Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.                                     |
| 8.B.3 Access exceptions (fetch) for second word of the header entry.   |
| 8.B.4 Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.   |
| 8.B.5 Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.  |
| 8.B.6 Stack-specification exception due to preceding entry being a header entry.   |
| 8.B.7 Stack-type exception due to preceding entry not being a state entry.   |
| 8.B.8 Access exceptions (fetch) for the selected contents of the state entry.  |

Figure 10-10. Priority of Execution: EXTRACT STACKED STATE

**Programming Note:** The results for a code of 1 in bit positions 56-63 of general register  $R_2$  are intended to provide compatibility with ESA/390. (It may be that only values of bits in bit positions 0-31 of the PSW are required.) Bit 63 of general register  $R_1 + 1$  is set to one if the instruction address in the PSW in the state entry is larger than a 31-bit address.

## **INSERT ADDRESS SPACE CONTROL**

IAC	$R_1$	[RRE]
'B224'		$R_1$

The address-space-control bits, bits 16 and 17 of the current PSW, are placed in reversed order in bit positions 54 and 55 of general register  $R_1$ ; that is, bit 16 is

placed in bit position 55, and bit 17 is placed in bit position 54. Bits 48-53 of the register are set to zeros, and bits 0-47 and 56-63 of the register remain unchanged. The address-space-control bits are also used to set the condition code.

### Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-11 on page 10-25.

### Resulting Condition Code:

- 0 PSW bits 16 and 17 zeros (indicating primary-space mode)
- 1 PSW bit 16 one and bit 17 zero (indicating secondary-space mode)
- 2 PSW bit 16 zero and bit 17 one (indicating access-register mode)
- 3 PSW bits 16 and 17 ones (indicating home-space mode)

### Program Exceptions:

- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation

- |       |  |
|-------|--|
| 1.-6. | Exceptions with the same priority as the priority of program-interruption conditions for the general case.                     |
| 7.A   | Access exceptions for second instruction halfword.   |
| 7.B   | Special-operation exception due to DAT being off.  |
| 8.    | Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state. |

### Programming Notes:

1. Bits 48-53 of general register R<sub>1</sub> are reserved for expansion for use with possible future facilities. The program should not depend on these bits being set to zeros.
2. INSERT ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL are defined to operate on the seventh byte of a general register so that the address-space-control bits can be saved in the same general register as the PSW key, which is placed in the eighth byte of general register 2 by INSERT PSW KEY.

## INSERT PSW KEY

IPK	[S]
'B20B'	
0	16
	31

The four-bit PSW-key, bits 8-11 of the current PSW, is inserted in bit positions 56-59 of general register 2, and bits 60-63 of that register are set to zeros. Bits 0-55 of general register 2 remain unchanged.

### Special Conditions

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Privileged operation (extraction-authority control is zero in the problem state)

## INSERT STORAGE KEY EXTENDED

ISKE	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B229'		R <sub>1</sub> R <sub>2</sub>
0	16	24 28 31

Figure 10-11. Priority of Execution: INSERT ADDRESS SPACE CONTROL

The storage key for the block that is addressed by the contents of general register R<sub>2</sub> is inserted in general register R<sub>1</sub>.

In the 24-bit addressing mode, bits 40-51 of general register R<sub>2</sub> designate a 4K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R<sub>2</sub> designate a 4K-byte block in real storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R<sub>2</sub> designate a 4K-byte block in real storage, and bits 52-63 of the register are ignored.

The address designating the storage block, being a real address, is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The seven-bit storage key is inserted in bit positions 56-62 of general register R<sub>1</sub>, and bit 63 is set to zero. The contents of bit positions 0-55 of the register remain unchanged.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Addressing (address specified by general register R<sub>2</sub>)
- Privileged operation

## INSERT VIRTUAL STORAGE KEY

IVSK	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B223'		R <sub>1</sub> R <sub>2</sub>

0                  16                  24                  28                  31

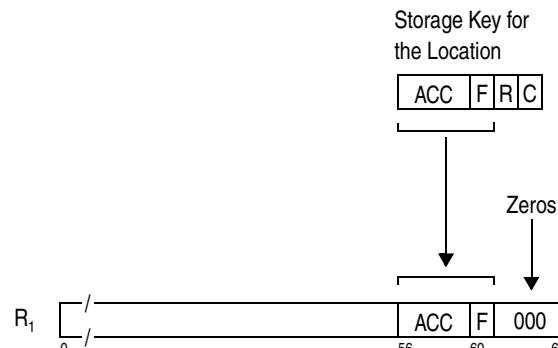

The storage key for the location designated by the virtual address in general register R<sub>2</sub> is inserted in general register R<sub>1</sub>.

Selected bits of general register R<sub>2</sub> are used as a virtual address. In the 24-bit addressing mode, the address is specified by bits 40-63 of the register, and bits 0-39 are ignored. In the 31-bit addressing mode, the address is specified by bits 33-63, and bits 0-32 are ignored. In the 64-bit addressing mode, the address is specified by bits 0-63 of the register.

The address is a virtual address and is subject to the address-space-control bits, bits 16 and 17 of the current PSW. The address is treated as a primary virtual address in the primary-space mode, as a secondary virtual address in the secondary-space mode, as an AR-specified virtual address in the access-register mode, or as a home virtual address in the home-space mode. The reference to the storage key is not subject to a protection exception.

Bits 0-4 of the storage key, which are the access-control bits and the fetch-protection bit, are placed in bit positions 56-60 of general register R<sub>1</sub>, with bits 61-63 set to zeros. The contents of bit positions 0-55 of the register remain unchanged. The change and reference bits in the storage key are not inspected. The change bit is not affected by the operation. The reference bit, depending on the model, may or may not be set to one as a result of the operation.

The following diagram shows the storage key and the register positions just described.

#### Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-12 on page 10-27.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (except for protection, address specified by general register R<sub>2</sub>)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off.
8.	Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero.
9.	Access exceptions (except for protection) for address specified by general register R <sub>2</sub> .

Figure 10-12. Priority of Execution: INSERT VIRTUAL STORAGE KEY

**Programming Notes:**

1. Since all bytes in a 4K-byte block are associated with the same page and the same storage key, bits 52-63 of general register R<sub>2</sub> essentially are ignored. Similarly, since all bytes in a 1M-byte block are associated with the same segment, bits 44-63 of general register R<sub>2</sub> may be ignored when enhanced DAT applies and the STE-format and ACCF-validity controls are both one.
2. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

**INVALIDATE DAT TABLE ENTRY**

IDTE	R <sub>1</sub> ,R <sub>3</sub> ,R <sub>2</sub>	[RRF]
0	'B98E'	R <sub>3</sub>   / / /   R <sub>1</sub> R <sub>2</sub> 16 20 24 28 31

When the clearing-by-ASCE-option bit, bit 52 of general register R<sub>2</sub>, is zero, an operation called the invalidation-and-clearing operation is performed, as follows. The designated region-table entry or segment-table entry in storage, or a range of entries beginning with the designated entry, is invalidated, and the translation-lookaside buffers (TLBs) in all CPUs in the configuration are cleared of (1) all combined region-and-segment-table entries (CRSTEs) and page-table entries (PTEs) formed through use of the invalidated entry or entries in storage and (2) all PTEs formed through use of a CRSTE formed through use of the invalidated entry or entries in storage. The TLB entries cleared may optionally be limited to entries formed to translate addresses in a specified address space.

When the clearing-by-ASCE-option bit is one, an operation called the clearing-by-ASCE operation is performed, as follows. The operation does not perform any invalidation of DAT-table entries in storage, but it does clear, from the TLBs in all CPUs in the configuration, all combined region-and-segment-table entries and page-table entries formed to translate addresses in a specified address space.

The two operations are described separately below, before the section “Common Operation.”

**Invalidation-and-Clearing Operation**

When bit 52 of general register R<sub>2</sub>, the clearing-by-ASCE-option bit, is zero, the invalidation-and-clearing operation is specified.

The contents of general register R<sub>1</sub> have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. The table origin designates the DAT table in which one or more entries are to be invalidated, and DT specifies the type of that table.

Bits 52-59, 62, and 63 of general register R<sub>1</sub> are ignored.

Bits 0-43 of general register R<sub>2</sub> have the format of the region index and segment index of a virtual address. The part of bits 0-43 normally used by DAT to select an entry in the type of table designated by general register R<sub>1</sub> is called the effective invalidation index.

Bits 60 and 61 of general register R<sub>1</sub> specify a table type and an effective invalidation index as follows:

Bits 60 and 61 of Reg. R <sub>1</sub>		Table Type	Effective Invalida tion Index in Reg. R <sub>2</sub>
11	Region first table	Region first index (bits 0-10)	
10	Region second table	Region second index (bits 11-21)	
01	Region third table	Region third index (bits 22-32)	
00	Segment table	Segment index (bits 33-43)	

The part of bits 0-43 of general register R<sub>2</sub> to the right of the effective invalidation index is ignored.

The table origin in general register R<sub>1</sub> and the effective invalidation index designate a DAT-table entry to

R <sub>1</sub>	Region-Table or Segment-Table Origin for Invalidation							/ / / / / / / DT / /
0								52 60 62 63
Note: The effective invalidation index is specified by DT in register R <sub>1</sub> .								
R <sub>2</sub>	Region-First Index	Region-Second Index	Region-Third Index	Segment Index	0 0 0 0 0 0 0 0	Additional Entries		
0	11	22	33	44	52 53	63		
Note: Used only if R <sub>3</sub> is nonzero.								
R <sub>3</sub>	Region-Table or Segment-Table Origin for Clearing							/ / / / / / / DT / /
0								52 60 62 63

Figure 10-13. Register Contents for INVALIDATE DAT TABLE ENTRY Invalidation-and-Clearing Operation (Bit 52 of GR R<sub>2</sub> Is Zero)

The table origin in general register R<sub>1</sub> and effective invalidation index in general register R<sub>2</sub> designate a table entry in accordance with the rules in “Lookup in a Table Designated by an Address-Space-Control Element” on page 3-48, except that a carry from bit position 0 of the resulting address is always ignored, and the index is not checked against a table-length field. The table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode specified by bits 31 and 32 of the current PSW. The address formed from these two components is a real or absolute address. The invalid bit, bit 58, of this region-table or segment-table entry is set to one. During this procedure, the entry is not checked for a format error or for whether the origin, in the entry, of the next-lower-level table would cause

be invalidated. Bits 53-63 of general register R<sub>2</sub> are an unsigned binary integer specifying the number of additional table entries to be invalidated. Therefore, the number of entries to be invalidated is 1-2,048, corresponding to a value of bits 53-63 of 0-2,047.

Bits 44-51 of general register R<sub>2</sub> must be zeros; otherwise, a specification exception is recognized.

If R<sub>3</sub> is nonzero, the contents of general register R<sub>3</sub> have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared. Bits 52-59, 62, and 63 of general register R<sub>3</sub> are ignored. If R<sub>3</sub> is zero, the entire contents of general register 0 are ignored.

The contents of the general registers just described are shown in Figure 10-13 on page 10-28.

an addressing exception. The table-type field in the entry is ignored. If the entry is a segment-table entry, the common-segment bit in the entry is ignored.

The entire table entry is fetched concurrently from storage. Subsequently, the byte containing the invalid bit is stored. The fetch access to the entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

If bits 53-63 of general register R<sub>2</sub> are not all zeros, the setting of the invalid bit to one in a region-table or segment-table entry is repeated by adding one to the previously used value of the effective invalidation index, and this is done as many times as are specified by bits 53-63. A carry out of the leftmost bit posi-

tion of the effective invalidation index is ignored, and wraparound in the table occurs in this case. The contents of general register R<sub>2</sub> remain unchanged.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

After it has set an invalid bit to one, this CPU clears selected entries from its TLB and signals all other CPUs in the configuration to clear selected entries from their TLBs. Each TLB is cleared of at least those combined region-and-segment-table entries (CRSTEs) for which all of the following conditions are met:

- The effective invalidation index and all bits to the left of it in general register R<sub>2</sub> match the same part of the region-and-segment-index field in the CRSTE. Note that when multiple table entries are invalidated due to bits 53-63 of general register R<sub>2</sub>, then the effective invalidation index is incremented, a carry out of the leftmost bit position of the index is lost, and CRSTEs are cleared for each value of the index so obtained.
- Either R<sub>3</sub> is zero or the table-origin and designation-type fields in general register R<sub>3</sub> match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the CRSTE. This ASCE is the one that attached the translation path from which the CRSTE was formed. See “Formation of TLB Entries” on page 3-53 for the meaning of the terminology used here.
- If the entry invalidated in storage is a segment-table entry, the page-table-origin field in the invalidated entry matches the page-table-origin field in the CRSTE.

Each TLB is also cleared of at least those page-table entries (PTEs) for which all of the following conditions are met:

- The TLB PTE was formed through use of an entry invalidated in storage or through use of a CRSTE formed through use of an entry invalidated in storage.
- Either R<sub>3</sub> is zero or the table-origin and designation-type fields in general register R<sub>3</sub> match the table-origin and designation-type fields in the

address-space-control element (ASCE) used to form the TLB PTE. This ASCE may be one that attached a translation path containing a segment-table entry that attached the PTE in storage from which the TLB PTE was formed, or it may be one that made usable a CRSTE that attached the PTE in storage from which the TLB PTE was formed. See “Formation of TLB Entries” on page 3-53 for the meaning of the terminology used here.

- If the entry invalidated in storage is a segment-table entry, the page-table-origin field in the invalidated entry matches the page-table-origin field in the TLB PTE.

Storing in the region- or segment-table entry and the clearing of TLB entries may or may not occur if the invalid bit is already one in the region- or segment-table entry.

When multiple entries are invalidated, clearing of TLB entries may be delayed until all entries have been invalidated.

### Clearing-by-ASCE Operation

When bit 52 of general register R<sub>2</sub>, the clearing-by-ASCE-option bit, is one, the clearing-by-ASCE operation is specified.

The contents of general register R<sub>3</sub> have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared. Bits 52-59, 62, and 63 of general register R<sub>3</sub> are ignored. R<sub>3</sub> may be zero or nonzero, that is, any general register, including register 0, may be designated.

Bits 44-51 of general register R<sub>2</sub> must be zeros; otherwise, a specification exception is recognized.

The contents of general register R<sub>1</sub> and of bit positions 0-43 and 53-63 of general register R<sub>2</sub> are ignored.

The contents of the general registers just described are shown in Figure 10-14 on page 10-30.

The TLBs of all CPUs in the configuration are cleared of at least those combined region-and-segment-table entries (CRSTEs) for which the table-origin and designation-type fields in general register R<sub>3</sub> match the

Figure 10-14. Register Contents for INVALIDATE DAT TABLE ENTRY Clearing-by-ASCE Operation (Bit 52 of GR R2 Is One)

table-origin and designation-type fields in the address-space-control element (ASCE) used to form the CRSTE. This ASCE is the one that attached the translation path from which the CRSTE was formed. See “Formation of TLB Entries” on page 3-53 for the meaning of the terminology used here.

Each TLB is also cleared of at least those page-table entries (PTEs) for which the table-origin and designation-type fields in general register R<sub>3</sub> match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the TLB PTE. This ASCE may be one that attached a translation path containing a segment-table entry that attached the PTE in storage from which the TLB PTE was formed, or it may be one that made usable a CRSTE that attached the PTE in storage from which the TLB PTE was formed. See “Formation of TLB Entries” on page 3-53 for the meaning of the terminology used here.

## Common Operation

When the clearing-by-ASCE-option bit, bit 52 of general register R<sub>2</sub>, is either zero or one, the execution of INVALIDATE DAT TABLE ENTRY is not completed on the CPU which executes it until (1) all entries corresponding to the specified parameters have been cleared from the TLB of this CPU and (2) all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits, by using TLB entries corresponding to the specified parameters.

The operations do not necessarily have any effect on TLB real-space entries.

## Special Conditions

Bits 44-51 of general register R<sub>2</sub> must be zeros; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions (invalidation-and-clearing operation only).

**Resulting Condition Code:** The code is unpredictable

## ***Program Exceptions:***

- Addressing (invalidated region- or segment-table entry, invalidation-and-clearing operation only).
  - Privileged operation
  - Operation (if the DAT-enhancement facility is not installed)
  - Protection (fetch and store, region- or segment-table entry, key-controlled protection and low-address protection; invalidation-and-clearing operation only).
  - Specification

## Programming Notes:

1. The selective clearing of TLB entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required. When the invalidation-and-clearing operation is performed, some models may clear all TLB entries when the effective invalidation index is not a segment index or may clear an entry regardless of the page-table origin in the entry. When that operation or the clearing-by-ASCE operation is performed, some models may clear a TLB entry regardless of the designation-type field in general register R<sub>3</sub>. When either operation is performed, other models may clear precisely the minimum number of entries required. Therefore, in order for a program to operate on all models, the program should not take advantage of any properties obtained by a less selective clearing on a particular model.

2. When using the clearing-by-ASCE operation to clear TLB entries associated with common segments, note that these entries may have been formed through use of address-space-control elements containing many different table origins.

The following notes apply when the invalidation-and-clearing operation is specified.

3. The clearing of TLB entries may make use of the page-table origin in a segment-table entry. Therefore, if the segment-table entry, when in the attached state, ever contained a page-table origin that is different from the current value, copies of entries containing the previous values may remain in the TLB.
4. INVALIDATE DAT TABLE ENTRY cannot be safely used to update a shared location in main storage if the possibility exists that another CPU or a channel program may also be updating the location.
5. The address of the DAT-table entry for INVALIDATE DAT TABLE ENTRY is a 64-bit address, and the address arithmetic is performed by following the normal rules for 64-bit address arithmetic, with wraparound at  $2^{64} - 1$ . Also, offset and length fields are not used. Contrast this with implicit translation and the translations for LOAD REAL ADDRESS and STORE REAL ADDRESS, all of which may result either in wraparound or in an addressing exception when a carry occurs out

of bit position 0 and which indicate an exception condition when the designated entry does not lie within its table. Accordingly, the DAT tables should not be specified to wrap from maximum storage locations to location 0, and the first designated entry and all additional entries specified by bits 53-63 of general register 3 should lie within the designated table.

## INVALIDATE PAGE TABLE ENTRY

IPTE	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B221'	R <sub>1</sub> R <sub>2</sub>	0 16 24 28 31

The designated page-table entry is invalidated, and the translation-lookaside buffers (TLBs) in all CPUs in the configuration are cleared of the associated entries.

The contents of general register R<sub>1</sub> have the format of a segment-table entry, with only the page-table origin used. The contents of general register R<sub>2</sub> have the format of a virtual address, with only the page index used. The contents of fields that are not part of the page-table origin or page index are ignored.

The contents of the general registers just described are shown in Figure 10-15 on page 10-31.

R <sub>1</sub>	Page-Table Origin	
0		53 63
R <sub>2</sub>		Page Index
0	44	52 63

Figure 10-15. Register Contents for INVALIDATE PAGE TABLE ENTRY

The page-table origin and the page index designate a page-table entry, following the dynamic-address-translation rules for page-table lookup. The page-table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode, which is specified by bits 31 and 32 of the current PSW. A carry out of bit position 0 as a result of the addition of the page index and page-table origin cannot occur. The address formed from these two components is a real or absolute address. The page-invalid bit of this page-table entry is set to one. During this procedure, the page-table entry is

not inspected for whether the page-invalid bit is already one or for format errors. Additionally, the page-frame real address contained in the entry is not checked for an addressing exception.

The entire page-table entry appears to be fetched concurrently from storage as observed by other CPUs. Subsequently, the byte containing the page-invalid bit is stored. The fetch access to the page-table entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

If no exceptions are recognized, this CPU clears selected entries from its TLB and signals all CPUs in the configuration to clear selected entries from their TLBs. Each TLB is cleared of at least those entries that have been formed using all of the following:

- The page-table origin specified by general register R<sub>1</sub>
- The page index specified by general register R<sub>2</sub>
- The page-frame real address contained in the designated page-table entry

The execution of INVALIDATE PAGE TABLE ENTRY is not completed on the CPU which executes it until (1) all entries corresponding to the specified parameters have been cleared from the TLB of this CPU and (2) all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits, by using TLB entries corresponding to the specified parameters.

### **Special Conditions**

The operation is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

### **Program Exceptions:**

- Addressing (page-table entry)
- Privileged operation
- Protection (fetch and store, page-table entry, key-controlled protection, and low-address protection)

### **Programming Notes:**

1. The selective clearing of entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required. Some models may clear all entries which contain the page-frame real address obtained from the page-table entry in storage. Others may clear all entries which contain the designated page index,

and some implementations may clear precisely the minimum number of entries required. Therefore, in order for a program to operate on all models, the program should not take advantage of any properties obtained by a less selective clearing on a particular model.

2. The clearing of TLB entries may make use of the page-frame real address in the page-table entry. Therefore, if the page-table entry, when in the attached state, ever contained a page-frame real address that is different from the current value, copies of entries containing the previous values may remain in the TLB.
3. INVALIDATE PAGE TABLE ENTRY cannot be safely used to update a shared location in main storage if the possibility exists that another CPU or a channel program may also be updating the location.

## **LOAD ADDRESS SPACE PARAMETERS**

LASP	D <sub>1</sub> (B <sub>1</sub> ),D <sub>2</sub> (B <sub>2</sub> )	[SSE]
'E500'	B <sub>1</sub> D <sub>1</sub> B <sub>2</sub> D <sub>2</sub>	0 16 20 32 36 47

The first operand contains values to be loaded into control registers 3 and 4, including a secondary ASN (SASN) and a primary ASN (PASN), and, possibly, a secondary ASTE instance number (SASTEIN) and a primary ASTE instance number (PASTEIN). Execution of the instruction consists in performing four major steps: PASN translation, SASN translation, SASN authorization, and control-register loading. Each of these steps may or may not be performed, depending on the outcome of certain tests and on the setting of bits 61-63 of the second-operand address. The first three of these steps, when performed and successful, obtain additional values, that are loaded into control registers 1, 5, and 7. When the first three steps are not successful when performed, no control registers are changed, and the reason is indicated in the condition code.

When the ASN-and-LX-reuse facility is not installed, or is installed but is not enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the first operand is a doubleword containing a PSW-key mask (PKM), a SASN, an authorization index (AX), and a PASN. When the ASN-and-LX-

reuse facility is installed and enabled, the first operand is two consecutive doublewords containing those four values and also a SASTEIN and a PASTEIN.

The primary ASN may be translated by means of the ASN-translation tables to obtain a primary-ASTE (PASTE) origin (PASTEO) and, from the PASTE, a primary ASCE (PASCE). The secondary ASN may be translated by means of the ASN-translation tables to obtain a secondary ASCE (SASCE). If the first operand is two doublewords and PASN or SASN translation occurs, the ASTEIN in the located ASTE is checked for being equal to the PASTEIN or SASTEIN, respectively, in the first operand. An authority check for ensuring that the new AX is authorized to establish the new SASN can be prevented when SASN translation occurs, or it can be required and cause SASN translation even when SASN translation would not otherwise occur. The new AX, which is placed in a control register and is used in SASN authorization if that occurs, is the old AX if PASN translation has not occurred or is the AX in the located PASTE otherwise. However, in either of these cases, the new AX may be the AX specified in the first operand.

A doubleword first operand has the following format:

First Operand if ASN-and-LX Reuse Is Not Enabled

PKM-d	SASN-d	AX-d	PASN-d
0	16	32	48

63

A two-doubleword first operand has the following format:

First Operand if ASN-and-LX Reuse Is Enabled

SASTEIN-d	PKM-d	SASN-d
0	32	48
PASTEIN-d	AX-d	PASN-d

64

96

112

127

The “d” stands for designated value and is used to distinguish these fields from other fields with similar names which are referred to in the definition. The current contents of the corresponding fields in the control registers are referred to as SASTEIN-old, PKM-old, SASN-old, etc. The updated contents of the control registers are referred to as SASTEIN-new, PKM-new, SASN-new, etc.

The second-operand address is not used to address data; instead, the rightmost three bits are used to

control portions of the operation. The remainder of the second-operand address is ignored. Bits 61-63 of the second-operand address are used as follows:

Bit	Function Specified in Second-Operand Address	
	When Bit Is Zero	When Bit Is One
61	ASN translation performed only when new ASN and old ASN are different.	ASN translation performed.*
62	AX associated with new PASN used.	AX in first operand used.
63	SASN authorization performed.*	SASN authorization not performed.

#### Explanation:

\* SASN translation and SASN authorization are performed only when SASN-d is not equal to PASN-d. When SASN-d is equal to PASN-d, the SASCE is set equal to the PASCE, the SASTEIN is set equal to the PASTEIN (if ASN-and-LX reuse is enabled), and no authorization is performed.

The operation of LOAD ADDRESS SPACE PARAMETERS is depicted in Figure 10-19 on page 10-41.

**Note:** In the following sections, the actions involving the PASTEIN and SASTEIN occur only if the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0.

#### PASN Translation and Related Processing

In the PASN-translation process, the PASN-d is translated by means of the ASN first table and the ASN second table. The PASTEO resulting from PASN translation replaces the PASTEO in control register 5. The ASCE in the located ASTE replaces the PASCE in control register 1. When bit 62 of the second-operand address is zero, the AX in the ASTE replaces the AX in control register 4. When bit 62 is one, AX-d replaces the AX in the control register. When ASN-and-LX reuse is enabled, PASTEIN-d is compared to the ASTEIN in the ASTE, and, when equal, replaces the PASTEIN in control register 4.

When bit 61 of the second-operand address is one, PASN translation is always performed. When bit 61 is zero, PASN translation is performed only if PASN-d is not equal to PASN-old. When bit 61 is zero and PASN-d is equal to PASN-old, the PASCE-old, PASTEO-old, and PASTEIN-old are left unchanged in the

control registers and become the PASCE-new, PASTEO-new, and PASTEIN-new, respectively. In this case, if bit 62 is zero, then the AX-old is left unchanged in the control register and becomes the AX-new, or, if bit 62 is one, AX-new is set equal to AX-d.

The PASN translation follows the normal rules for ASN translation, except that the invalid bits, bit 0 in the ASN-first-table entry and bit 0 in the ASTE, when ones, do not result in an ASN-translation exception. When either of the invalid bits is one, condition code 1 is set. Condition code 1 is also set if PASN translation occurs, the ASN-and-LX-reuse facility is enabled, and PASTEIN-d is not equal to the ASTEIN in the ASTE. When a reason for setting condition code 1 does not exist and either the current primary space-switch-event-control bit in control register 1 is one or the space-switch-event-control bit in the ASTE is one, a space-switch event does not occur; instead, condition code 3 is set. When condition code 1 or 3 is set, the control registers remain unchanged.

The contents of the AX, ASCE, and ASTEIN fields in the ASTE which is accessed as a result of the PASN translation are referred to as AX-p, ASCE-p, and ASTEIN-p, respectively. The origin of the ASTE is referred to as PASTEO-p.

The description in this paragraph applies to use of the subspace-group facility. After ASCE-p has been obtained, if (1) the subspace-group-control bit, bit 54 in ASCE-p, is one, (2) the dispatchable unit is subspace active, and (3) PASTEO-p designates the ASTE for the base space of the dispatchable unit, then a copy of ASCE-p, called ASCE-rp, is made, and bits 0-55 and 58-63 of ASCE-rp are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in "Subspace-Replacement Operations" on page 5-66. If bit 0 in the subspace ASTE is one, or if the ASTE sequence number (ASTESN) in the subspace ASTE does not equal the subspace ASTESN in the dispatchable-unit control table, an exception is not recognized; instead, condition code 1 is set, and the control registers remain unchanged.

### SASN Translation and Related Processing

In the SASN-translation process, the SASN-d is translated by means of the ASN first table and the ASN second table. The ASCE field obtained from the ASTE subsequently replaces the secondary ASCE (SASCE) in control register 7. When ASN-and-LX

reuse is enabled, SASTEIN-d is compared to the ASTEIN in the ASTE, and, when equal, replaces the SASTEIN in control register 3.

SASN translation is performed only when, but not necessarily when, SASN-d is not equal to PASN-d. When SASN-d is equal to PASN-d, SASCE-new and SASTEIN-new are set equal to PASCE-new and PASTEIN-new, respectively. In this case, there is not a test of whether SASTEIN-d is equal to PASTEIN-d; SASTEIN-d is ignored. When SASN-d is not equal to PASN-d and is equal to SASN-old, bit 61 (force ASN translation) is zero, and bit 63 (skip SASN authorization) is one, SASN translation is not performed, and SASCE-old and SASTEIN-old become SASCE-new and SASTEIN-new, respectively. In this case, there is not a test of whether SASTEIN-d is equal to SASTEIN-old; SASTEIN-d is ignored.

SASN translation is performed in each of the following cases:

- SASN-d is not equal to PASN-d or SASN-old.
- SASN-d is not equal to PASN-d but is equal to SASN-old, and either bit 61 (force ASN translation) of the second-operand address is one or bit 63 (skip secondary authority test) of that address is zero. (The translation must be performed when bit 63 is zero in order to obtain the ATO and ATL from the ASTE.)

The SASN translation follows the normal rules for ASN translation, except that the invalid bits, bit 0 in the ASN-first-table entry and bit 0 in the ASTE, when ones, do not result in an ASN-translation exception. When either of the invalid bits is one, condition code 2 is set. Condition code 2 is also set if SASN translation occurs, the ASN-and-LX-reuse facility is enabled, and SASTEIN-d is not equal to the ASTEIN in the ASTE. When condition code 2 is set, the control registers remain unchanged.

The contents of the ASCE, ATO, ATL and ASTEIN fields in the ASTE which is accessed as a result of the SASN translation are referred to as ASCE-s, ATO-s, ATL-s, and ASTEIN-s, respectively. The origin of the ASTE is referred to as SASTEO-s.

The description in this paragraph applies to use of the subspace-group facility. After ASCE-s has been obtained, if (1) the subspace-group-control bit, bit 54 in ASCE-s, is one, (2) the dispatchable unit is subspace active, and (3) SASTEO-s designates the

ASTE for the base space of the dispatchable unit, then a copy of ASCE-s, called ASCE-rs, is made, and bits 0-55 and 58-63 of ASCE-rs are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-66. If bit 0 in the subspace ASTE is one, or if the ASTE sequence number (ASTESN) in the subspace ASTE does not equal the subspace ASTESN in the dispatchable-unit control table, an exception is not recognized; instead, condition code 2 is set, and the control registers remain unchanged.

### SASN Authorization

SASN authorization is performed when bit 63 of the second-operand address is zero and SASN-d is not equal to PASN-d; it is performed in this case regardless of whether SASN-d is equal to SASN-old. When SASN-d is equal to PASN-d or when bit 63 of the second-operand address is one, SASN authorization is not performed.

SASN authorization is performed by using ATO-s, ATL-s, and the intended value for AX-new. When bit 62 of the second-operand address is zero and PASN translation was performed, the intended value for AX-new is AX-p. When bit 62 of that address is zero and PASN translation was not performed, the AX is not changed, and AX-new is the same as AX-old. When bit 62 of that address is one, the intended value for AX-new is AX-d. SASN authorization follows the rules for secondary authorization as described in “ASN-Authorization Process” on page 3-32. If the SASN is not authorized (that is, the authority-table length is exceeded, or the selected bit is zero), condition code 2 is set, and none of the control registers is updated.

### Control-Register Loading

When the PASN-translation and SASN-translation functions and related functions, and the SASN-authorization functions and subspace-replacement operations, if called for in the instruction execution, are performed without encountering any exceptions or exception conditions, the execution is completed by replacing the contents of control registers 1, 3, 4, 5, and 7 with the new values, and condition code 0 is set. The control registers are loaded as follows.

The PSW-key-mask, bits 32-47, and SASN, bits 48-63, in control register 3 are replaced by the con-

tents of the PKM-d and SASN-d fields of the first operand.

If ASN-and-LX reuse is enabled, the SASTEIN, bits 0-31, in control register 3 is replaced as follows:

- When SASN translation is performed, by SASTEIN-d.
- When SASN translation is not performed because SASN-d is equal to PASN-d, by PASTEIN-new.
- When SASN translation is not performed because (1) SASN-d is not equal to PASN-d but is equal to SASN-old, (2) bit 61 (force ASN translation) of the second-operand address is zero, and (3) bit 63 (skip secondary authority test) of the second-operand address is one, the SASTEIN remains unchanged.

When ASN-and-LX reuse is not enabled, bits 0-31 of control register 3 always remain unchanged.

The PASN, bits 48-63 of control register 4, is replaced by the PASN-d of the first operand. If ASN-and-LX reuse is enabled, the PASTEIN, bits 0-31 of control register 4, is replaced by the PASTEIN-d of the first operand; otherwise, bits 0-31 of the register remain unchanged.

The authorization index, bits 32-47 of control register 4, is replaced as follows:

- When bit 62 of the second-operand address is one, by AX-d.
- When bit 62 of the second-operand address is zero and PASN translation is performed, by AX-p.
- When bit 62 of the second-operand address is zero and PASN translation is not performed, the authorization index remains unchanged.

The primary address-space-control element (PASCE) in control register 1 and the primary-ASN-second-table-entry origin (PASTEO) in control register 5 are replaced as follows:

- When PASN translation is performed, the PASCE in control register 1 is replaced by the ASCE-p obtained as a result of PASN translation, except that it is replaced by ASCE-rp if a subspace-replacement operation was performed on

ASCE-p. Also, the PASTEO in control register 5 is replaced by PASTEO-p.

The PASTEO-p is placed in bit positions 33-57 of control register 5, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of the register remain unchanged.

- When PASN translation is not performed, the contents of control registers 1 and 5 remain unchanged.

The secondary address-space-control element (SASCE) in control register 7 is replaced as follows:

- When SASN-d equals PASN-d, by the new contents of control register 1, the PASCE. The new contents may be PASCE-old, ASCE-p, or ASCE-rp.
- When SASN translation is performed, by ASCE-s, or by ASCE-rs if a subspace-replacement operation was performed on ASCE-s.

When SASN-d does not equal PASN-d and SASN translation is not performed, the SASCE remains unchanged.

### Other Condition-Code Settings

When PASN translation is called for and cannot be completed because bit 0 is one in either the ASN-first-table entry or the ASTE, or if it can be completed but (1) ASN-and-LX reuse is enabled and PASTEIN-d does not equal the ASTEIN in the ASTE or (2) a subspace-replacement-exception condition exists due to bit 0 or the ASTE sequence number in the subspace ASTE during a subspace-replacement operation on the ASCE-p, condition code 1 is set, and the control registers are not changed.

When PASN translation is called for and completed and any required PASTEIN-d comparison and subspace-replacement operations on the ASCE-p are also completed, and then either (1) the current primary space-switch-event-control bit, bit 57 of control register 1, is one or (2) the space-switch-event-control bit in the ASTE designated by PASTEO-p is one, condition code 3 is set, and the control registers are not changed.

When SASN translation is called for and the translation cannot be completed because bit 0 is one in either the ASN-first-table entry or the ASTE, or if it can be completed but (1) ASN-and-LX reuse is

enabled and SASTEIN-d does not equal the ASTEIN in the ASTE, (2) a subspace-replacement-exception condition exists due to bit 0 or the ASTE sequence number in the subspace ASTE during a subspace-replacement operation on the ASCE-s, or (3) SASN authorization is called for and the SASN is not authorized, or condition code 2 is set, and the control registers are not changed.

### Special Conditions

The instruction can be executed only when the ASN-translation control, bit 44 of control register 14, is one. If the ASN-translation-control bit is zero, a special-operation exception is recognized.

The first operand must be designated on a double-word boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

Figure 10-18 on page 10-40 and Figure 10-16 on page 10-38 summarize the functions of the instruction and the priority of recognition of exceptions and condition codes.

#### ***Resulting Condition Code:***

- Translation and authorization complete; parameters loaded
- Primary ASN or subspace not available; parameters not loaded
- Secondary ASN not available or not authorized, or secondary subspace not available; parameters not loaded
- Space-switch event specified; parameters not loaded

#### ***Program Exceptions:***

- Access (fetch, operand 1)
- Addressing (ASN-first-table entry, ASN-second-table entry, authority-table entry, dispatchable-unit control table)
- Privileged operation
- Special operation
- Specification

#### ***Programming Notes:***

- Bits 61 and 63 in the second-operand address are intended primarily to provide improved per-

formance for those cases where the associated action is unnecessary.

When bit 61 is set to zero, the action of the instruction is based on the assumption that the current values for PASCE-old, PASTEO-old, and AX-old are consistent with PASN-old and that SASCE-old is consistent with SASN-old. When this is not the case, bit 61 should be set to one.

Bit 63, when one, eliminates the SASN-authorization test. The program may be able to determine in certain cases that the SASN is authorized, either because of prior use or because the AX being loaded is authorized to access all address spaces.

2. The SASN-translation and SASN-authorization steps are not performed when SASN-d is equal to PASN-d. This is consistent with the action in SET SECONDARY ASN to current primary (SSAR-cp), which does not perform the translation or ASN authorization.
3. The storage-operand references for LOAD ADDRESS SPACE PARAMETERS may be multiple-access references. (See “Storage-Operand Consistency” on page 5-95.)
4. See Figure 10-17 on page 10-39 for a listing of abbreviations used in this instruction description.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second and third instruction halfwords.
7.B.1	Privileged-operation exception.
7.B.2	Special-operation exception due to the ASN-translation control, bit 44 of control register 14, being zero.
8.	Specification exception.
9.	Access exceptions for the first operand.
10.	PASN translation and related processing (when performed).
10.1	Addressing exception for access to ASN-first-table entry.
10.2	Condition code 1 due to I bit (bit 0) in ASN-first-table entry being one.
10.3	Addressing exception for access to ASN-second-table entry.
10.4	Condition code 1 due to (1) I bit (bit 0) in ASN-second-table entry (ASTE) being one or (2) ASN-and-LX reuse enabled and primary ASTE instance number (PASTEIN) in first operand not being equal to ASTEIN in ASTE.
10.5	Addressing exception for access to dispatchable-unit control table.
10.6	Addressing exception for access to subspace ASN-second-table entry.
10.7	Condition code 1 due to I bit (bit 0) in subspace ASN-second-table entry being one.
10.8	Condition code 1 due to subspace ASN-second-table-entry sequence number (SSASTESN) in dispatchable-unit control table not being equal to ASTESN in subspace ASN-second-table entry.
10.9	Condition code 3 due to either the old or new space-switch-event-control bit being one.
11.	SASN translation and related processing (when performed).
11.1	Addressing exception for access to ASN-first-table entry.
11.2	Condition code 2 due to I bit (bit 0) in ASN-first-table entry being one.
11.3	Addressing exception for access to ASN-second-table entry.
11.4	Condition code 2 due to (1) I bit (bit 0) in ASN-second-table entry (ASTE) being one or (2) ASN-and-LX reuse enabled and secondary ASTE instance number (SASTEIN) in first operand not being equal to ASTEIN in ASTE.
12.A	Execution of secondary authorization (when performed).
12.A.1	Condition code 2 due to authority-table entry being outside table.
12.A.2	Addressing exception for access to authority-table entry.
12.A.3	Condition code 2 due to S bit in authority-table entry being zero.
12.B.1	Addressing exception for access to dispatchable-unit control table.
12.B.2	Addressing exception for access to subspace ASN-second-table entry.
12.B.3	Condition code 2 due to I bit (bit 0) in subspace ASN-second-table entry being one.
12.B.4	Condition code 2 due to subspace ASN-second-table-entry sequence number (SSASTESN) in dispatchable-unit control table not being equal to ASTESN in subspace ASN-second-table entry.

No	Yes	-	0	Yes	Yes	ASCE-s <sup>4</sup>	SASTEIN-d
No	No	-	1	Yes	No	ASCE-s <sup>4</sup>	SASTEIN-d
No	No	-	0	Yes	Yes	ASCE-s <sup>4</sup>	SASTEIN-d

**Explanation:**

- Action in this case is the same regardless of the outcome of this comparison or of the setting of this bit.

<sup>1</sup> Second-operand-address bits:

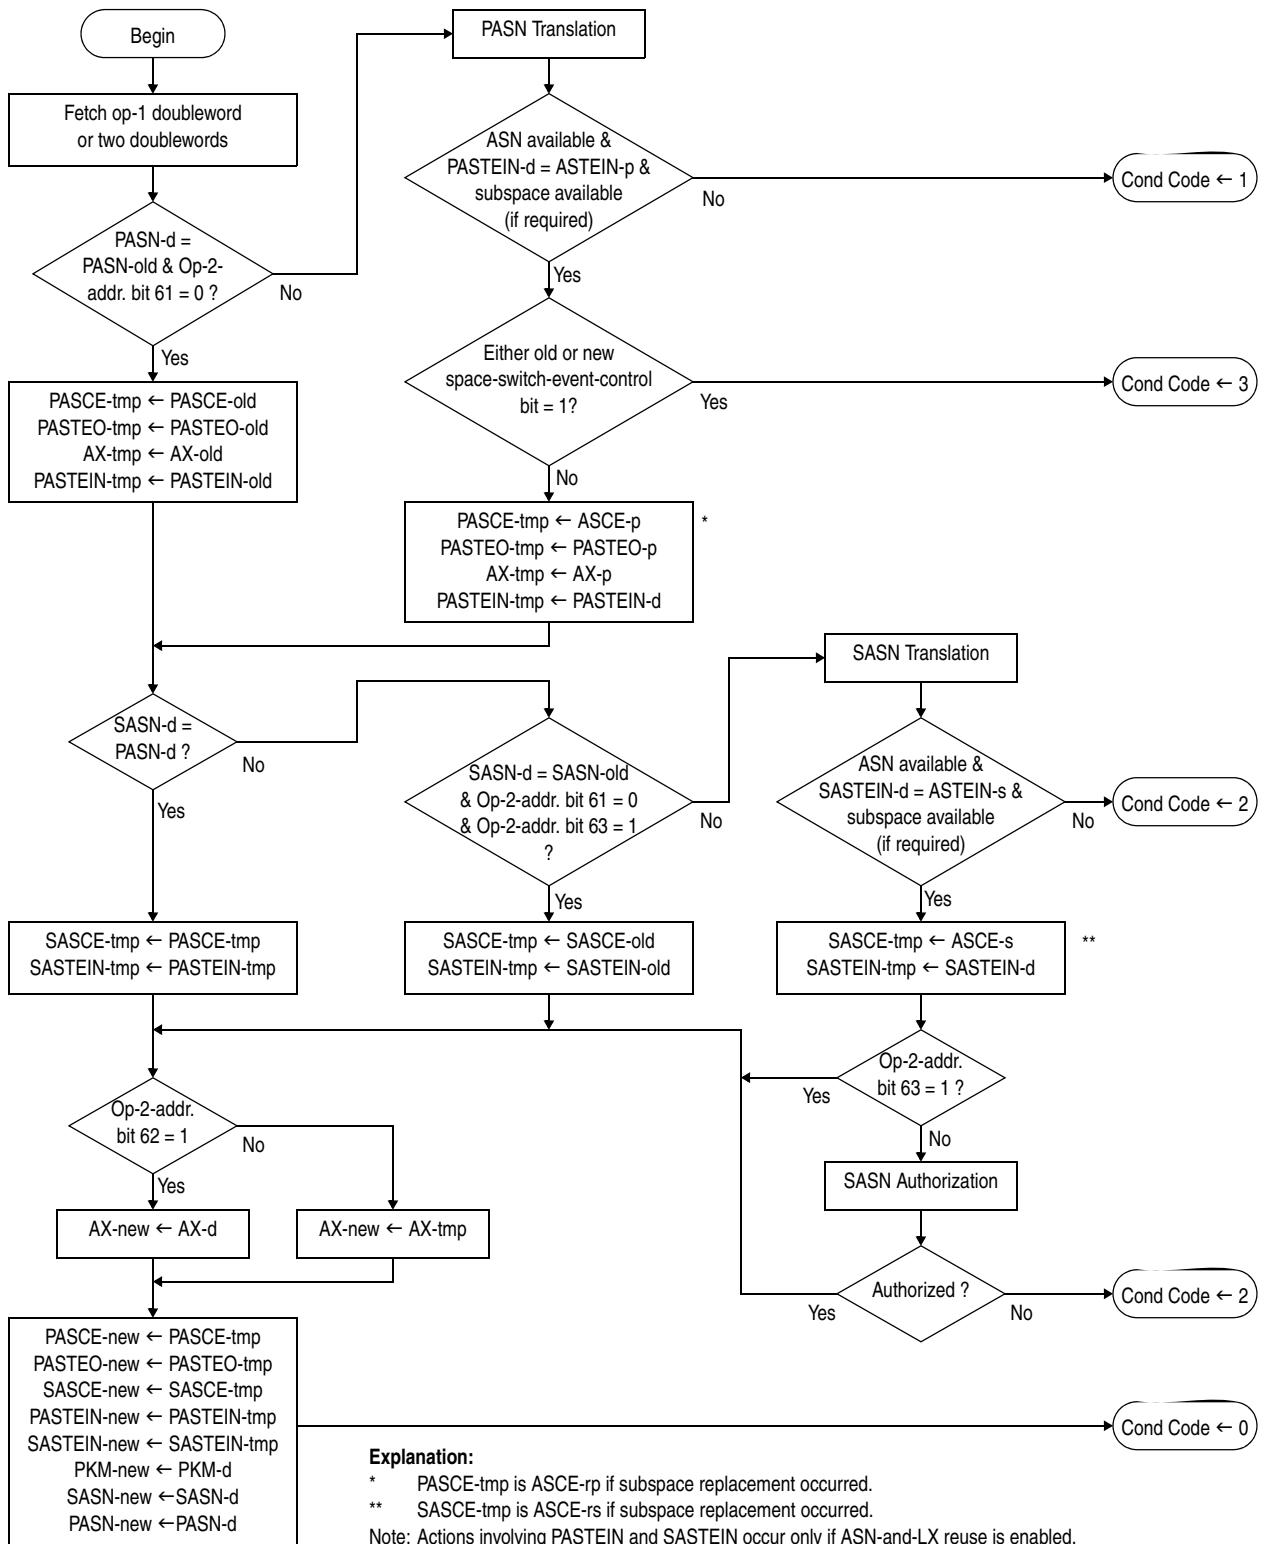

- 61 Force ASN translation.
- 62 Use AX from first operand.
- 63 Skip secondary authority test.

<sup>2</sup> PASCE-new is ASCE-rp (a copy of ASCE-p except with bits 0-55 and 58-63 replaced from the ASCE in the subspace ASTE), if subspace replacement is performed.

<sup>3</sup> ASN authorization is performed using ATO-s, ATL-s, and AX-new.

<sup>4</sup> SASCE-new is ASCE-rs (a copy of ASCE-s except with bits 0-55 and 58-63 replaced from the ASCE in the subspace ASTE), if subspace replacement is performed.

Figure 10-18. Summary of Actions: LOAD ADDRESS SPACE PARAMETERS (Part 2 of 2).

*Figure 10-19. Execution of LOAD ADDRESS SPACE PARAMETERS*

## LOAD CONTROL

LCTL	R <sub>1</sub> ,R <sub>3</sub> ,D <sub>2</sub> (B <sub>2</sub> )	[RS]
'B7'	R <sub>1</sub> R <sub>3</sub> B <sub>2</sub>	D <sub>2</sub>

0      8      12      16      20      31

LCTLG	R <sub>1</sub> ,R <sub>3</sub> ,D <sub>2</sub> (B <sub>2</sub> )	[RSY]
'EB'	R <sub>1</sub> R <sub>3</sub> B <sub>2</sub>	DL <sub>2</sub> DH <sub>2</sub> '2E'

0      8      12      16      20      32      40      47

Bit positions of the set of control registers starting with control register R<sub>1</sub> and ending with control register R<sub>3</sub> are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed.

For LOAD CONTROL (LCTL), bit positions 32-63 of the control registers are loaded from successive words beginning at the second-operand address, and bits 0-31 of the registers remain unchanged. For LOAD CONTROL (LCTLG), bit positions 0-63 of the control registers are loaded from successive doublewords beginning at the second-operand address. The control registers are loaded in ascending order of their register numbers, starting with control register R<sub>1</sub> and continuing up to and including control register R<sub>3</sub>, with control register 0 following control register 15.

The information loaded into the control registers becomes active when instruction execution has ended.

The displacement for LCTL is treated as a 12-bit unsigned binary integer. The displacement for LCTLG is treated as a 20-bit signed binary integer.

### Special Conditions

The second operand must be designated on a word boundary for LCTL or on a doubleword boundary for LCTLG; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification

### Programming Notes:

- To ensure that existing programs operate correctly if and when new facilities using additional control-register positions are defined, only zeros should be loaded in unassigned control-register positions.
- Loading of control registers on some models may require a significant amount of time. This is particularly true for changes in significant parameters.

For example, the TLB may be cleared of entries as a result of changing or enabling the program-event-recording parameters in control registers 9-11. Where possible, the program should avoid unnecessary loading of control registers. In loading control registers 9-11, most models attempt to optimize for the case when the bits of control register 9 are zeros.

## LOAD PAGE-TABLE-ENTRY ADDRESS

LPTEA	R <sub>1</sub> ,R <sub>3</sub> ,R <sub>2</sub> ,M <sub>4</sub>	[RRF]
'B9AA'	R <sub>3</sub> M <sub>4</sub> R <sub>1</sub> R <sub>2</sub>	0      16      20      24      28      31

General register R<sub>2</sub> contains a virtual address that is processed by means of dynamic address translation to locate a page-table entry, the 64-bit real or absolute address of which is returned in general register R<sub>1</sub>. The M<sub>4</sub> field contains a value designating the effective address-space-control element (ASCE) that is used by DAT, as shown in the following table:

M4 Field (binary)	Effective Address-Space-Control Element Used by DAT
0000	Contents of control register 1
0001	The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the R2 field.
0010	Contents of control register 7
0011	Contents of control register 13
0100	The address-space-control element corresponding to the current address-space-control bits, bits 16 and 17 of the PSW.

When the  $M_4$  field contains 0001 binary, or when the  $M_4$  field contains 0100 binary and bits 16-17 of the PSW contain 01 binary, then access-register translation precedes, as is normal, the dynamic address translation.

The  $R_3$  field is ignored but should be zero to permit possible future extensions.

The virtual address specified by the  $R_2$  field is translated by means of dynamic-address translation, regardless of whether DAT is on or off. ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively. The DAT process completes upon locating the page-table entry. The contents of the page-table entry are not examined for format errors, the I bit is not examined to determine whether the page is invalid, and the page-frame real address is not fetched.

Virtual address computation is performed according to the addressing mode specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry are treated as 64-bit addresses, regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

If the DAT process successfully locates the page-table entry, the 64-bit real or absolute address of the entry is placed in general register  $R_1$ , and the condition code is set as follows:

- When enhanced DAT does not apply, the condition code is set based on the DAT-protection bit (P) of the segment-table entry used in the translation. Condition code 0 is set when the P bit is zero; condition code 1 is set when the P bit is one.
- When enhanced DAT applies, the condition code is set based on all of the DAT-protection bits encountered in the translation. If the DAT-protec-

tion bit is zero in the segment-table entry and the DAT-protection bits are zero in any and all region-table entries used in the translation, condition code 0 is set. If the DAT-protection bit is one in any region- or segment-table entry used in the translation, condition code 1 is set.

When enhanced DAT applies and the DAT process successfully locates a valid segment-table entry in which the STE-format control is one, bits 0-60 of the segment-table entry address are placed in bit positions 0-60 of general register  $R_1$ , bit 61 of the register is set to the logical OR of the DAT-protection bit in the segment-table entry and any region-table entries used in the translation, bits 62-63 of the register are set to zeros, and the instruction completes by setting condition code 2.

When a condition exists that would normally cause one of the exceptions shown in Figure 10-20, processing is as follows:

1. General register  $R_1$  is updated as follows:
  - a. Bits 0-60 of the table-entry address are placed in bit positions 0-60 of the register.
  - b. When enhanced DAT does not apply, bit 61 of the register is set to zero. When enhanced DAT applies, bit 61 is set to the logical OR of the DAT-protection bits in all valid region-table entries used in the translation; if the DAT process does not require region-table entries, or if no valid region-table entries are encountered, bit 61 is set to zero.
  - c. The expected table-type bits are placed in bit positions 62-63 of the register. When the region table or segment table containing the invalid entry is directly designated by the address-space-control element, then the expected table-type bits are those contained in the designation-type control (DT) in the ASCE. Otherwise, the expected table-type bits are one less than the value of those bits in the next-higher-level table.

2. The instruction is completed by setting condition code 2 .

Exception Name	Cause	Code (hex)	Expected TT Bits
Region first translation	Invalid bit is one in the region-first-table entry selected by the RFX portion of the virtual address.	0039	11
Region second translation	Invalid bit is one in the region-second-table entry selected by the RSX portion of the virtual address.	003A	10
Region third translation	Invalid bit is one in the region-third-table entry selected by the RTX portion of the virtual address.	003B	01
Segment translation	Invalid bit is one in the segment-table entry selected by the SX portion of the virtual address.	0010	00

| *Figure 10-20. LPTEA Exception Conditions Causing CC2*

When a condition exists that would normally cause one of the exceptions shown in Figure 10-21, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register  $R_1$ , and bits 0-47 of the register are set to zeros; and (2) the instruction is completed by setting condition code 3.

Exception Name	Cause	Code (hex)
ALET specification	ALET bits 0-6 not all zeros.	0028
ALEN translation	ALE outside list or I bit is one.	0029
ALE sequence	ALESN in ALET not equal to ALESN in ALE.	002A
ASTE validity	ASTE I bit is one.	002B
ASTE sequence	ASTESN in ALE not equal to ASTESN in ASTE.	002C
Extended authority	ALE P bit not zero, ALEAX not equal to EAX, and secondary bit selected by EAX either outside authority table or zero.	002D

| *Figure 10-21. LPTEA Exception Conditions Causing CC3*

Exception Name	Cause	Code (hex)
ASCE type	ASCE is a region-second-table designation, and bits 0-10 of virtual address not all zeros; ASCE is a region-third-table designation, and bits 0-21 of virtual address not all zeros; or ASCE is a segment-table designation, and bits 0-32 of virtual address not all zeros.	0038
Region first translation	Region-first-table entry selected by RFX portion of virtual address outside table.	0039
Region second translation	Region-second-table entry selected by RSX portion of virtual address outside table.	003A
Region third translation	Region-third-table entry selected by RTX portion of virtual address outside table.	003B
Segment translation	Segment-table entry selected by SX portion of virtual address outside table.	0010

*Figure 10-21. LPTEA Exception Conditions Causing CC3*

### Special Conditions

If the  $M_4$  field contains any value other than 0000-0100 binary, a specification exception is recognized.

The address-space-control element used in the translation must not be a real-space designation; otherwise, a special-operation exception is recognized. The exception due to the address-space-control element has priority 9 in Figure 6-6 on page 6-44.

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation, the access-list entry, the address-space-second-table entry, or the authority-table entry designates a location which is not available in the configuration. An addressing exception is also recognized when the address used by DAT to fetch a region-table entry or the segment-table entry designates a location which is not available in the configuration.

A carry out of bit position 0 as a result of the addition done to compute the address of a region-table entry or the segment-table entry may be ignored or may result in an addressing exception.

A translation-specification exception is recognized if an accessed region-table entry or the segment-table entry has a zero I bit and a format error.

The operation is suppressed on all addressing exceptions.

#### **Resulting Condition Code:**

- 0 PTE address returned; STE P bit is 0
- 1 PTE address returned; STE P bit is 1
- 2 Invalid bit is one in the region- or segment-table entry, or enhanced DAT applies, a valid STE was located, and STE FC is 1
- 3 Exception condition exists

#### **Program Exceptions:**

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, or segment-table entry)
- Operation (DAT-enhancement facility 2 not installed)
- Privileged operation
- Special operation
- Specification
- Translation specification

#### **Programming Notes:**

1. An addressing exception is not recognized if the page-table-entry address returned in general register R<sub>1</sub> is not available in the configuration.
2. When enhanced DAT applies, the STE-format control is one, and no other exception conditions apply, the address of the segment-table entry is placed in general register R<sub>1</sub>, and condition code 2 is set. This effectively performs a *load-segment-table-entry-address* function, although no such instruction is defined.

However, because condition code 2 is also used to indicate an invalid region-table entry or segment-table entry, all of the following conditions must exist in order to assume that the located table entry is a valid STE:

- a. Bit positions 62-63 of general register R<sub>1</sub> (the expected table-type) must contain 00 binary.
- b. Bit position 58 of the table entry designated by general register R<sub>1</sub> must contain zero (indicating a valid table entry).

- c. The table-type field in bit positions 60-61 of the table entry designated by general register R<sub>1</sub> must contain 00 binary (designating a segment-table entry).

The following program fragment illustrates this determination. If no branch is taken, then the address in general register 1 is that of a segment-table entry in which the STE-format control is one:

LPTEA	1,0,2,4
BRC	8,PTE_WITH_NEITHER_STE_NOR_RTE_PROT
BRC	4,PTE_WITH_PROTECTED_STE_OR_RTE
BRC	1,EXCEPTION_EXISTS
TMLL	1,X'0003'
BRNZ	NOT_STE
NILL	1,X'FFF8'
LG	10,0,(1)
TMLL	10,X'002C'
BRNZ	INVALID_OR_MALFORMED_STE

3. When condition code 2 is set as a result of locating a valid segment-table entry in which the STE-format control is one, bit 61 of general register R<sub>1</sub> indicates whether DAT protection applies to the segment.

## **LOAD PSW**

LPSW	D <sub>2</sub> (B <sub>2</sub> )	[S]
'82'	B <sub>2</sub> D <sub>2</sub>	0 16 20 31

The current PSW is replaced by a 16-byte PSW formed from the contents of the doubleword at the location designated by the second-operand address.

Bit 12 of the doubleword must be one; otherwise, a specification exception may be recognized, depending on the model.

Bits 0-32 of the doubleword, except with bit 12 inverted, are placed in bit positions 0-32 of the current PSW. Bits 33-63 of the doubleword are placed in bit positions 97-127 of the current PSW. Bits 33-96 of the current PSW are set to zeros.

A serialization and checkpoint-synchronization function is performed before or after the operand is fetched and again after the operation is completed.

## Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized. A specification exception may be recognized if bit 12 of the operand is zero, depending on the model.

The PSW fields which are to be loaded by the instruction are not checked for validity before they are loaded, except for the optional checking of bit 12. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, when any of the following is true for the newly loaded PSW:

- Any of bits 0, 2-4, 12, or 24-30 is a one.
- Bits 31 and 32 are both zero, and bits 97-103 are not all zeros.
- Bits 31 and 32 are one and zero, respectively.

In these cases, the operation is completed, and the resulting instruction-length code is 0.

The test for a specification exception after the PSW is loaded is described in “Early Exception Recognition” on page 6-8. It may be considered as occurring early in the process of preparing to execute the subsequent instruction.

The operation is suppressed on all addressing and protection exceptions.

**Resulting Condition Code:** The code is set as specified in the new PSW loaded.

### Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification

**Programming Note:** The second operand should have the format of an ESA/390 PSW. A specification exception will be recognized during or after the execution of LOAD PSW if bit 12 of the operand is zero.

## LOAD PSW EXTENDED

LPSWE	D <sub>2</sub> (B <sub>2</sub> )	[S]
	'B2B2'	B <sub>2</sub>
0	16	20

The current PSW is replaced by the contents of the 16-byte second operand.

A serialization and checkpoint-synchronization function is performed before or after the operand is fetched and again after the operation is completed.

### Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

The value which is to be loaded by the instruction is not checked for validity before it is loaded. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, when any of the following is true for the newly loaded PSW:

- Any of the unassigned bits (0, 2-4, 24-30, or 33-63) is a one.
- Bit 12 is a one.
- Bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros.
- Bits 31 and 32 are both zero, and bits 64-103 are not all zeros.
- Bits 31 and 32 are one and zero, respectively.

In these cases, the operation is completed, and the resulting instruction-length code is zero.

The test for a specification exception after the PSW is loaded is described in “Early Exception Recognition” on page 6-8. It may be considered as occurring early in the process of preparing to execute the subsequent instruction.

The operation is suppressed on all addressing and protection exceptions.

**Resulting Condition Code:** The code is set as specified in the new PSW loaded.

### Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification

## LOAD REAL ADDRESS

LRA	$R_1, D_2(X_2, B_2)$				[RX]
'B1'	$R_1$	$X_2$	$B_2$	$D_2$	
0	8	12	16	20	31

LRAY	$R_1, D_2(X_2, B_2)$				[RXY]
'E3'	$R_1$	$X_2$	$B_2$	$DL_2$	$DH_2$
0	8	12	16	20	40 47

LRAG	$R_1, D_2(X_2, B_2)$				[RXY]
'E3'	$R_1$	$X_2$	$B_2$	$DL_2$	$DH_2$
0	8	12	16	20	32 40 47

For LOAD REAL ADDRESS (LRA, LRAY) in the 24-bit or 31-bit addressing mode, if bits 0-32 of the 64-bit real or absolute address corresponding to the second-operand virtual address are all zeros, bits 32-63 of the real or absolute address are placed in bit positions 32-63 of general register  $R_1$ , and bits 0-31 of the register remain unchanged. If bits 0-32 of the real address or absolute are not all zeros, a special-operation exception is recognized.

For LRA or LRAY in the 64-bit addressing mode, and for LOAD REAL ADDRESS (LRAG) in any addressing mode, the 64-bit real or absolute address corresponding to the second-operand virtual address is placed in general register  $R_1$ .

When the enhanced-DAT facility is not installed, or when the facility is installed but the second operand is translated by means of a segment-table entry in which the STE-format control is zero, the address placed in general register  $R_1$  is real. When the enhanced-DAT facility is installed and the second operand is translated by means of a segment-table entry in which the STE-format control is one, the address placed in general register  $R_1$  is absolute.

The virtual address specified by the  $X_2$ ,  $B_2$ , and  $D_2$  fields is translated by means of the dynamic-address-translation facility, regardless of whether DAT is on or off.

The displacement for LRA is treated as a 12-bit unsigned binary integer. The displacement for LRAY and LRAG is treated as a 20-bit signed binary integer.

DAT is performed by using an address-space-control element that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW, as shown in the following table:

PSW Bits	Address-Space-Control Element
16 and 17	Used by DAT
00	Contents of control register 1
10	Contents of control register 7
01	The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the $B_2$ field
11	Contents of control register 13

ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively.

The virtual-address computation is performed according to the current addressing mode, specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry, if used, are treated as 64-bit addresses regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

Condition code 0 is set when both ART, if applicable, and DAT can be completed and a special-operation exception is not recognized, that is, when an address-space-control element can be obtained, the entry in each DAT table lies within the table and has a zero I bit, and, for LRA or LRAY in the 24-bit or 31-bit addressing mode, bits 0-32 of the resulting real or absolute address are zeros. The translated address is not inspected for boundary alignment or for addressing or protection exceptions.

When PSW bits 16 and 17 are 01 binary and an address-space-control element cannot be obtained because of a condition that would normally cause one of the exceptions shown in the following table, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register  $R_1$ , bit 32 of this register is set to one, bits 33-47 are set

to zeros, and bits 0-31 remain unchanged, and (2) the instruction is completed by setting condition code 3.

Exception Name	Cause	Code (Hex)
ALET specification	Access-list-entry-token (ALET) bits 0-6 not all zeros	0028
ALEN translation	Access-list entry (ALE) outside list or invalid (bit 0 is one)	0029
ALE sequence	ALE sequence number (ALESN) in ALET not equal to ALESN in ALE	002A
ASTE validity	ASN-second-table entry (ASTE) invalid (bit 0 is one)	002B
ASTE sequence	ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE	002C
Extended authority	ALE private bit not zero, ALE authorization index (ALEAX) not equal to extended authorization index (EAX), and secondary bit selected by EAX either outside authority table or zero	002D

When ART is completed normally, the operation is continued through the performance of DAT.

When the segment-table entry is outside the table and bits 0-32 of the real or absolute address of the entry are all zeros, condition code 3 is set, bits 32-63 of the entry address are placed in bit positions 32-63 of general register R<sub>1</sub>, and bits 0-31 of the register remain unchanged. If bits 0-32 of the address are not all zeros, the result is as shown in the next table below.

For LRA or LRAY in the 64-bit addressing mode or LRG in any addressing mode, when the I bit in the segment-table entry is one, condition code 1 is set, and the 64-bit real or absolute address of the segment-table entry is placed in general register R<sub>1</sub>. In this case except that LRA or LRAY is in the 24-bit or 31-bit addressing mode, if bits 0-32 of the address of the segment-table entry are all zeros, the result is the same except that bits 0-31 of general register R<sub>1</sub> remain unchanged. If bits 0-32 of the address are not all zeros, the result is as shown in the next table below.

For LRA or LRAY in the 64-bit addressing mode or LRG in any addressing mode, when the I bit in the page-table entry is one, condition code 2 is set, and the 64-bit real or absolute address of the page-table

entry is placed in general register R<sub>1</sub>. In this case except that LRA or LRAY is in the 24-bit or 31-bit addressing mode, if bits 0-32 of the address of the page-table entry are all zeros, the result is the same except that bits 0-31 of general register R<sub>1</sub> remain unchanged. If bits 0-32 of the address are not all zeros, the result is as shown in the next table below.

A segment-table-entry or page-table-entry address placed in general register R<sub>1</sub> is real or absolute in accordance with the type of address that was used during the attempted translation.

If a condition exists that would normally cause one of the exceptions shown in the following table, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register R<sub>1</sub>, bit 32 of this register is set to one, bits 33-47 are set to zeros, and bits 0-31 remain unchanged, and (2) the instruction is completed by setting condition code 3.

Exception Name	Cause	Code (Hex)
ASCE type	Address-space-control element (ASCE) being used is a region-second-table designation, and bits 0-10 of virtual address not all zeros; ASCE is a region-third-table designation, and bits 0-21 of virtual address not all zeros; or ASCE is a segment-table designation, and bits 0-32 of virtual address not all zeros.	0038
Region first translation	Region-first-table entry selected by region-first-index portion of virtual address outside table or invalid.	0039
Region second translation	Region-second-table entry selected by region-second-index portion of virtual address outside table or invalid.	003A
Region third translation	Region-third-table entry selected by region-third-index portion of virtual address outside table or invalid.	003B
Segment translation	Segment-table entry selected by segment-index portion of virtual address outside table (only when bits 0-32 of entry address not all zeros); or segment-table entry invalid (LRA and LRAY only, and only in 24-bit or 31-bit addressing mode when bits 0-32 of entry address not all zeros).	0010

Exception Name	Cause	Code (Hex)
Page translation	Page-table entry selected by page-index portion of virtual address invalid (LRA and LRAY only, and only in 24-bit or 31-bit addressing mode when bits 0-32 of entry address not all zeros).	0011

### Special Conditions

A special-operation exception is recognized when, for LRA or LRAY in the 24-bit or 31-bit addressing mode, bits 0-32 of the resultant 64-bit real address are not all zeros.

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration or when the address used to fetch the region-table entry or entries, if any, segment-table entry, or page-table entry designates a location which is not available in the configuration.

A translation-specification exception is recognized when an accessed region-table entry or the segment-table entry or page-table entry has a zero I bit and a format error, that is, when any of the reasons listed in "Translation-Specification Exception" on page 6-39 applies.

A carry out of bit position 0 as a result of the addition done to compute the address of a region-table entry or the segment-table entry may be ignored or may result in an addressing exception.

The operation is suppressed on all addressing exceptions.

### Resulting Condition Code:

- 0 Translation available
- 1 Segment-table entry invalid (I bit one)
- 2 Page-table entry invalid (I bit one)
- 3 Address-space-control element not available, region-table entry outside table or invalid (I bit one), segment-table entry outside table, or, for LRA and LRAY only, and only in 24-bit or 31-bit addressing mode when bits 0-32 of entry

address not all zeros, segment-table entry or page-table entry invalid (I bit one)

### Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, segment-table entry, or page-table entry)
- Operation (LRAY, if the long-displacement facility is not installed)
- Privileged operation
- Special operation (LRA, LRAY only)
- Translation specification

### Programming Notes:

1. Caution must be exercised in the use of LOAD REAL ADDRESS in a multiprocessing configuration. Since INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY may set I bits in storage to one before causing the corresponding entries in TLBs of other CPUs to be cleared, the simultaneous execution of LOAD REAL ADDRESS on this CPU and either INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY on another CPU may produce inconsistent results. Because LOAD REAL ADDRESS may access the tables in storage, the segment-table entry or page-table entry may appear to be invalid (condition code 1 or 2, respectively) even though the corresponding TLB entry has not yet been cleared, and the TLB entry may remain in the TLB until the completion of INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY on the other CPU. There is no guaranteed limit to the number of instructions which may be executed between the completion of LOAD REAL ADDRESS and the TLB being cleared of the entry.

The above cautions for using LOAD REAL ADDRESS also apply when COMPARE AND SWAP AND PURGE is used to explicitly set the invalid bit in a DAT-table entry.

2. Figure 10-22 on page 10-50 summarizes the resulting contents of general register R<sub>1</sub> and the condition code.

Exception/Cause/ Entry-Address Size or Resultant-Real- Address Size	General Register R <sub>1</sub> Contents and Condition Code									
	LRA or LRAY in 24-Bit or 31-Bit Addressing Mode					LRA or LRAY in 64-Bit Addr. Mode or LRAG in Any Addressing Mode

**Explanation:**

EA1 Bits 0-31 of the entry address.  
 EA2 Bit 32 of the entry address.  
 EA3 Bits 33-47 of the entry address.  
 EA4 Bits 48-63 of the entry address.  
 RA1 Bits 0-31 of the resultant real address.  
 RA2 Bit 32 of the resultant real address.  
 RA3 Bits 33-47 of the resultant real address.  
 RA4 Bits 48-63 of the resultant real address.  
 U Unchanged.

Figure 10-22. Summary of Results: LOAD REAL ADDRESS

## LOAD USING REAL ADDRESS

LURA	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B24B'	R <sub>1</sub> R <sub>2</sub>	
0	16 24 28 31	

LURAG	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B905'	R <sub>1</sub> R <sub>2</sub>	
0	16 24 28 31	

For LOAD USING REAL ADDRESS (LURA), the word at the real-storage location addressed by the contents of general register R<sub>2</sub> is placed in bit positions 32-63 of general register R<sub>1</sub>, and the contents of bit positions 0-31 remain unchanged. For LOAD USING REAL ADDRESS (LURAG), the doubleword at that real-storage location is placed in bit positions 0-63 of general register R<sub>1</sub>.

In the 24-bit addressing mode, bits 40-63 of general register R<sub>2</sub> designate the real-storage location, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, bits 33-63 of general register R<sub>2</sub> designate the real-storage location, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, bits 0-63 of general register R<sub>2</sub> designate the real-storage location.

Because it is a real address, the address designating the storage word or doubleword is not subject to dynamic address translation.

### Special Conditions

The contents of general register R<sub>2</sub> must designate a location on a word boundary for LURA or on a doubleword boundary for LURAG; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Addressing (address specified by general register R<sub>2</sub>)
- Privileged operation
- Protection (fetch, operand 2, key-controlled protection)
- Specification

## MODIFY STACKED STATE

MSTA	R <sub>1</sub>	[RRE]
'B247'	R <sub>1</sub> ////	
0	16 24 28 31	

The contents of bit positions 32-63 of the pair of general registers designated by the R<sub>1</sub> field are placed in the modifiable area, byte positions 152-159, of the last state entry in the linkage stack.

The R<sub>1</sub> field designates the even-numbered register of an even-odd pair of general registers.

The last state entry is located as described in “Unstacking Process” on page 5-82. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

Key-controlled protection does not apply to the references to the linkage stack, but low-address and DAT protection do apply.

### Special Conditions

A specification exception is recognized when R<sub>1</sub> is odd.

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-23 on page 10-52.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch and store, except for key-controlled protection, linkage-stack entry)
- Special operation
- Specification
- Stack empty

- Stack specification
- Stack type

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode.
8.A	Specification exception due to $R_1$ being odd.
8.B.1	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.
8.B.2	Stack-type exception due to current entry not being a state entry or header entry. <b>Note:</b> Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.
8.B.3	Access exceptions (fetch) for second word of the header entry.
8.B.4	Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.
8.B.5	Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.
8.B.6	Stack-specification exception due to preceding entry being a header entry.
8.B.7	Stack-type exception due to preceding entry not being a state entry.
8.B.8	Access exceptions (store) for the modifiable area of the state entry.

Figure 10-23. Priority of Execution: MODIFY STACKED STATE

## MOVE PAGE

MVPG	$R_1, R_2$	[RRE]
'B254'		$R_1$ $R_2$
0	16 24 28	31

The first operand is replaced by the second operand. The first and second operands both are 4K bytes on 4K-byte boundaries. The results are indicated in the condition code. The accesses to the first-operand location or the second-operand location, but not to both locations, may be performed by using the key specified in general register 0; otherwise, the accesses to an operand location are performed by using the PSW key.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers  $R_1$  and  $R_2$ , respectively.

The handling of the addresses in general registers  $R_1$  and  $R_2$  depends on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-51 of a general register, with 12 rightmost zeros

appended, are the address, and bits 0-39 and 52-63 in the register are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 0-32 and 52-63 in the register are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 52-63 in the register are ignored.

Bits 56-59 of general register 0 are used as the specified access key. Bit 52 of general register 0, when one, specifies that the specified access key is to be used for accessing the first operand, and bit 53 specifies the same for the second operand. A specification exception is recognized if bits 52 and 53 are both ones. Bit 54 of general register 0 is a destination-reference-intention bit, and bit 55 is a condition-code-option bit. Bits 48-51 of general register 0 must be zeros; otherwise, a specification exception is recognized. Bits 0-47 and 60-63 of general register 0 are ignored.

The contents of the registers just described are shown in Figure 10-24 on page 10-53.

### **Explanation:**

CCO	Condition-code-option bit.
DRI	Destination-reference-intention bit.
F	When one, specified access key applies to first operand. A specification exception is recognized if F and S both are one.
Key	Specified access key.
S	When one, specified access key applies to second operand. A specification exception is recognized if F and S both are one.

*Figure 10-24. Register Contents for MOVE PAGE*

When bit 52 of general register 0 is one, the fetch accesses to the second-operand location are performed by using the PSW key, and the store accesses to the first-operand location are performed by using the key specified in general register 0. When bit 53 of general register 0 is one, the fetch accesses to the second-operand location are performed by using the key specified in general register 0, and the store accesses to the first-operand location are performed by using the PSW key. When bits 52 and 53 are both zeros, the PSW key is used for accessing both operands.

When 4K bytes have been moved, condition code 0 is set

When a page-translation-exception condition exists, the exception is not recognized if the condition-code-option bit, bit 55 in general register 0, is one; instead,

condition code 1 or 2 is set. Condition code 1 is set if a page-translation-exception condition exists for the first operand and not for the second operand. Condition code 2 is set if a page-translation-exception condition exists for the second operand, regardless of whether the condition exists for the first operand.

When an access exception can be recognized for both operands, it is unpredictable for which operand an exception is recognized. If one of the exceptions is a page-translation exception that would cause condition code 1 or 2 to be set, it is unpredictable whether the access exception for the other operand is recognized or condition code 1 or 2 is set.

The references to main storage are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

## Special Conditions

In the problem state, when either bit 52 or bit 53 in general register 0 is one, the operation is performed only if the access key specified in general register 0 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid. When bits 52 and 53 are both zeros, the access key in general register 0 is not tested for validity.

In the problem state, when bits 52 and 53 in general register 0 are both ones and the access key in general register 0 is not permitted by the PSW-key mask, it is unpredictable whether a specification exception or a privileged-operation exception is recognized.

### *Resulting Condition Code:*

- 0 Data moved
- 1 Condition-code-option bit one, page-table entry for first operand invalid, and page-table entry for second operand valid
- 2 Condition-code-option bit one and page-table entry for second operand invalid
- 3 --

### *Program Exceptions:*

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (access key specified, and selected PSW-key-mask bit is zero in the problem state)
- Specification

### *Programming Notes:*

1. MOVE PAGE, or a loop of MOVE PAGE instructions that moves multiple pages, may provide, on most models, better performance than a MOVE LONG instruction or a loop of MOVE (MVC) instructions that performs the same function. Whether MOVE PAGE provides better performance depends on control-program specifications and the method by which the control program handles page-translation exceptions.
2. The destination-reference-intention bit should be set to one when there is an intention to reference the first operand by means of an instruction other than MOVE PAGE. The bit may allow the control

program to process a page-translation exception more efficiently.

3. The condition-code-option bit provides compatibility with the MOVE PAGE instruction of the ESA/390 move-page facility 1. The bit is for use by the MVS/ESA HPSERV macro expansion.
4. The condition code set by the instruction normally need not be examined if the condition-code-option bit is zero or if DAT is off..
5. See the definitions of real locations 162 and 168-175 under "Assigned Storage Locations" in Chapter 3, "Storage" for a description of information stored during a program interruption due to a DAT-related translation exception recognized by MOVE PAGE.

## MOVE TO PRIMARY

MVCP	$D_1(R_1, B_1), D_2(B_2), R_3$							[SS]
'DA'	R <sub>1</sub>	R <sub>3</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>		
0	8	12	16	20	32	36	47	

## MOVE TO SECONDARY

MVCS	$D_1(R_1, B_1), D_2(B_2), R_3$							[SS]
'DB'	R <sub>1</sub>	R <sub>3</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>		
0	8	12	16	20	32	36	47	

The first operand is replaced by the second operand. One operand is in the primary address space, and the other is in the secondary address space. The accesses to the operand in the primary space are performed by using the PSW key; the accesses to the operand in the secondary space are performed by using the key specified by the third operand.

The addresses of the first and second operands are virtual, one operand address being translated by means of the primary address-space-control element and the other by means of the secondary address-space-control element. Operand-address translation is performed in the same way when the address-space-control bits in the current PSW specify either the primary-space mode or the secondary-space mode.

For MOVE TO PRIMARY, movement is to the primary space from the secondary space. The first-operand address is translated by using the primary address-

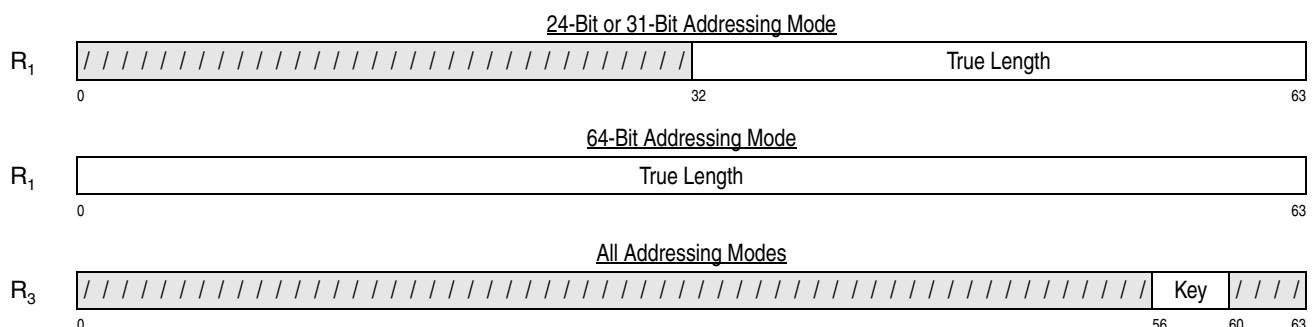

space-control element, and the second-operand address is translated by using the secondary address-space-control element.

For MOVE TO SECONDARY, movement is to the secondary space from the primary space. The first-operand address is translated by using the secondary address-space-control element, and the second-operand address is translated by using the primary address-space-control element.

Bit positions 56-59 of general register R<sub>3</sub> are used as the secondary-space access key. Bit positions 0-55 and 60-63 of the register are ignored.

General register R<sub>1</sub> contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-25 on page 10-55.

*Figure 10-25. Register Contents of MOVE TO PRIMARY and MOVE TO SECONDARY*

The first and second operands are the same length, called the effective length. The effective length is equal to the true length or 256, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

Each storage operand is processed left to right. The storage-operand-consistency rules are the same as for MOVE (MVC), except that when the operands overlap in real storage, the use of the common real-storage locations is not necessarily recognized.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 256 or less, including zero, the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 256, the effective length is 256, and condition code 3 is set.

For both MOVE TO PRIMARY and MOVE TO SECONDARY, a serialization and checkpoint-synchronization

zation function is performed before the operation begins and again after the operation is completed.

### **Special Conditions**

Since the secondary space is accessed, the operation is performed only when the secondary-space control, bit 37 of control register 0, is one and DAT is on. When either the secondary-space control is zero or DAT is off, a special-operation exception is recognized. A special-operation exception is also recognized when the address-space-control bits in the current PSW specify the access-register or home-space mode.

In the problem state, the operation is performed only if the secondary-space access key is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the secondary-space access key is valid.

The priority of the recognition of exceptions and condition codes is shown in Figure 10-26 on page 10-56.

### *Resulting Condition Code:*

- 0 True length less than or equal to 256
  - 1 --
  - 2 --
  - 3 True length greater than 256

## ***Program Exceptions:***

- Access (fetch, primary virtual address, operand 2, MVCS; fetch, secondary virtual address, operand 2, MVCP; store, secondary virtual address, operand 1, MVCS; store, primary virtual address, operand 1, MVCP)
  - Privileged operation (selected PSW-key-mask bit is zero in the problem state)
  - Special operation

- 1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.
- 7.A Access exceptions for second and third instruction halfwords.
- 7.B Special-operation exception due to the secondary-space control, bit 37 of control register 0, being zero, to DAT being off, or to the CPU being in the access-register or home-space mode.
- 8. Privileged-operation exception due to selected PSW-key-mask bit being zero in the problem state.
- 9. Completion due to length zero.
- 10. Access exceptions for operands.

*Figure 10-26. Priority of Execution: MOVE TO PRIMARY and MOVE TO SECONDARY*

## Programming Notes:

1. MOVE TO PRIMARY and MOVE TO SECONDARY can be used in a loop to move a variable

GR0		L
	0	56
GR1		Key
	0	56

*Figure 10-27. Register Contents of MOVE WITH DESTINATION KEY*

L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

number of bytes of any length. See the programming note under MOVE WITH KEY.

2. MOVE TO PRIMARY and MOVE TO SECONDARY should be used only when movement is between different address spaces. The performance of these instructions on most models may be significantly slower than that of MOVE WITH KEY, MOVE (MVC), or MOVE LONG. In addition, the definition of overlapping operands for MOVE TO PRIMARY and MOVE TO SECONDARY is not compatible with the more precise definitions for MOVE (MVC), MOVE WITH KEY, and MOVE LONG.

# MOVE WITH DESTINATION KEY

MVCSDK	$D_1(B_1), D_2(B_2)$	[SSE]
'E50F'	$B_1$	$D_1$
0	16	20
	32	36
	47	

The first operand is replaced by the second operand. The accesses to the destination-operand location are performed by using the key specified in general register 1, and the accesses to the source-operand location are performed by using the PSW key.

The first and second operands are of the same length, which is specified by bits 56-63 of general register 0. Bits 0-55 of general register 0 are ignored.

Bits 56-59 of general register 1 are used as the specified access key. Bits 0-55 and 60-63 of general register 1 are ignored.

The contents of general registers 0 and 1 are shown in Figure 10-27 on page 10-56.

L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

The fetch accesses to the second-operand location are performed by using the PSW key, and the store accesses to the first-operand location are performed by using the key specified in general register 1.

Each of the operands is processed left to right. When the operands overlap destructively in real storage, the results in the first-operand location are unpredictable. Except for this unpredictability in the case of destructive overlap, the storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

## **Special Conditions**

In the problem state, the operation is performed only if the access key specified in general register 1 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid.

**Condition Code:** The code remains unchanged.

## ***Program Exceptions:***

- Access (fetch, operand 2; store, operand 1)
  - Privileged operation (selected PSW-key-mask bit is zero in the problem state)

**Programming Note:** See the programming notes for the MOVE WITH SOURCE KEY instruction.

# MOVE WITH KEY

MVCK	$D_1(R_1, B_1), D_2(B_2), R_3$	[SS]					
'D9'	R <sub>1</sub>	R <sub>3</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>	
0	8	12	16	20	32	36	47

The first operand is replaced by the second operand. The fetch accesses to the second-operand location are performed by using the key specified in the third operand, and the store accesses to the first-operand location are performed by using the PSW key.

Bit positions 56-59 of general register R<sub>3</sub> are used as the source access key. Bit positions 0-55 and 60-63 of the register are ignored.

General register R<sub>1</sub> contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-28 on page 10-57.

*Figure 10-28. Register Contents of MOVE WITH KEY*

The first and second operands are of the same length, called the effective length. The effective length is equal to the true length or 256, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

Each storage operand is processed left to right.  
When the storage operands overlap, the result is

obtained as if the operands were processed one byte at a time and each result byte were stored immediately after the necessary operand byte was fetched. The storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 256 or less, including zero, the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 256,

the effective length is 256, and condition code 3 is set.

### Special Conditions

In the problem state, the operation is performed only if the source access key is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the source access key is valid.

The priority of the recognition of exceptions and condition codes is shown in Figure 10-29 on page 10-58.

### Resulting Condition Code:

- 0 True length less than or equal to 256
- 1 --
- 2 --
- 3 True length greater than 256

### Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second and third instruction halfwords.
8.	Privileged-operation exception due to selected PSW-key-mask bit being zero in the problem state.
9.	Completion due to length zero.
10.	Access exceptions for operands.

Figure 10-29. Priority of Execution: MOVE WITH KEY

### Programming Notes:

1. MOVE WITH KEY can be used in a loop to move a variable number of bytes of any length, as follows:

```

LOOP      MVCK  D1(R1,B1),D2(B2),R3
          BC    8,END
          AHI   B1,256
          AHI   B2,256
          AHI   R1,-256
          B     LOOP
END      [Any instruction]

```

The above program is for execution in the 24-bit or 31-bit addressing mode. In the 64-bit addressing mode, AGHI instructions should be substituted for the AHI instructions.

2. The performance of MOVE WITH KEY on most models may be significantly slower than that of the MOVE (MVC) and MOVE LONG instructions. Therefore, MOVE WITH KEY should not be used if the keys of the source and the target are the same.

## MOVE WITH OPTIONAL SPECIFICATIONS

MVCOS	[SSF]							
	'C8'	R <sub>3</sub>	'0'	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>	
	0	8	12	16	20	32	36	47

The first operand is replaced by the second operand. Bits in general register 0 determine the address-space-control modes and protection keys that are used to access the first and second operands.

The addresses of the first and second operands are virtual.

Bits 32-47 of general register 0 contain the operand-access control for the first operand ( $OAC_1$ ), and bits 48-63 of general register 0 contain the operand-access control for the second operand ( $OAC_2$ ). The operand-access control has the following format.

Key	/ / / /	AS	/ / / /	KA
0	4	8	10	14 15

**Specified-Access Key (Key):** Bits positions 0-3 contain the specified-access key that is used to

access the operand if the specified-access-key validity bit (K) is one; otherwise, the specified-access key is ignored.

**Specified-Address-Space Control (AS):** Bit positions 8-9 contain the address-space control that is used to access the operand when the specified-address-space-control validity bit (A) is one; otherwise, the specified-address-space control is ignored. The meaning of bits 8-9 is identical to that of the address-space control in bits 16-17 of the PSW.

**Specified-Access-Key Validity Bit (K):** Bit 14 controls whether the PSW key or the specified-access key is used to access the operand. When the K bit is zero, the PSW key is used. When the K bit is one, the specified-access key is used.

**Specified-Address-Space-Control Validity Bit (A):** Bit 15 controls whether the address-space control in the current PSW or the address-space control in the specified-ASC is used to access the oper-

and. When the A bit is zero, the address-space control in the current PSW is used. When the A bit is one, the specified-address-space control is used.

Bits 0-31 of general register 0 are ignored. Bits 4-7 and 10-14 of both operand-access controls (that is, bits 36-39, 42-45, 52-55, and 58-61 of general register 0) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register R<sub>3</sub> contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-30.

*Figure 10-30. Register Contents for MOVE WITH OPTIONAL SPECIFICATIONS*

The first and second operands are the same length, called the effective length. The effective length is equal to the true length or 4,096, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 4,096 or less, including zero, then the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 4,096, then the effective length is 4,096, and condition code 3 is set.

No test is made for destructive overlap, and the results in the first-operand location are unpredictable when destructive overlap exists. Operands are said to overlap destructively when the first-operand real location is used as a source after data has been moved into it.

Operands do not overlap destructively if the leftmost byte of the first operand does not coincide with any of the second-operand bytes participating in the operation other than the leftmost byte of the second operand. When an operand wraps around from location  $2^{24} - 1$  (or  $2^{31} - 1$  or  $2^{64} - 1$ ) to location 0, operand bytes in locations up to and including  $2^{24} - 1$  (or  $2^{31} - 1$  or  $2^{64} - 1$ ) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location  $2^{24} - 1$  to location 0; in the 31-bit addressing mode, wraparound is from location  $2^{31} - 1$  to location 0; and, in the 64-bit addressing mode, wraparound is from location  $2^{64} - 1$  to location 0.

### Special Conditions

A special-operation exception is recognized for any of the following conditions:

- DAT is off.
- The address-space control in OAC<sub>1</sub> designates the home-space mode, the address-space-control validity bit in OAC<sub>1</sub> is one, and the current PSW is in the problem state (that is, bits 40-41 of general register 0 are 11 binary, bit 47 of the register is one, and bit 15 of the current PSW is one).
- The secondary-space control, bit 37 of control register 0, is zero, and either of the following is true:
  - The A bit of the OAC for either operand is zero, and bits 16-17 of the current PSW are 10 binary.
  - The A bit of the OAC for either operand is one, and the AS bits in the same OAC are 10 binary.

The secondary-space control is not examined for an operand that is accessed in the secondary-space mode as a result of access-register translation (that is, DAT is on, bits 16-17 of the current PSW are 01 binary, and the access register corresponding to the operand's base register contains an ALET of 00000001 hex).

When MOVE WITH OPTIONAL SPECIFICATIONS is executed in the problem state, and either the first or second operand's specified-access key (from GR0) or the implied-access key (from the PSW) is invalid, a privileged-operation exception is recognized. The validity of an access key is determined as follows:

- The specified-access key in OAC<sub>1</sub> is invalid if the specified-access-key control, bit 46 of general register 0, is one; and the specified-access key, bits 32-35 of the register, designates a PSW-key-mask (PKM) bit position in control register 3 that contains zero.

- The specified-access key in OAC<sub>2</sub> is invalid if the specified-access-key control, bit 62 of general register 0, is one; and the specified-access key, bits 48-51 of the register, designates a PKM bit position that contains zero.
- The implied-access key is invalid if both of the following conditions are true:
  - Either or both bits 46 and 62 of general register 0 are zero.
  - The PSW key, bits 8-11 of the PSW, designates a PKM bit position that contains zero.

In the supervisor state, any value for the implied- or specified-access key is valid.

The priority of the recognition of exceptions and condition codes is shown in Figure 10-31.

### Resulting Condition Code:

- |   |   |
|---|---|
| 0 | True length less than or equal to 4,096 |
| 1 | --                                      |
| 2 | --                                      |
| 3 | True length greater than 4,096          |

### Program Exceptions:

- Access (fetch, second operand; store first operand)
- Operation (MVCOS not installed)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Special operation

1.-5.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
6.1	Access exceptions for first instruction halfword.
6.2.A	Access exceptions for second instruction halfword.
6.2.B	Access exceptions for third instruction halfword.
7.	Operation exception.
8.	Special-operation exception.
9.	Privileged-operation exception.
10.	Completion due to length zero.
11.	Access exceptions for operands.

Figure 10-31. Priority of Execution: MOVE WITH OPTIONAL SPECIFICATIONS

## Programming Notes:

1. MOVE WITH OPTIONAL SPECIFICATIONS can be used in a loop to move a variable number of bytes of any length.
  2. An example of moving 16 K-bytes to the home address space from the secondary address space is shown below. The first operand is accessed using the PSW key, and the second operand is accessed using key 5.

```

LA      3,OPERAND1
LA      5,OPERAND2
LHI    7,16384
LLILF  0,X'00C15083'
LOOP   MVCOS 0(3),0(5),7
          AHI    3,4096
          AHI    5,4096
          AHI    7,-4096
          BP     LOOP

```

In the 64-bit addressing mode, AGHI instructions should be substituted for the AHI instructions.

3. The performance of MOVE WITH OPTIONAL SPECIFICATIONS may be significantly slower than that of individual MOVE (MVC) instructions.
  4. When bits 46-47 and 62-63 of general register 0 are all zero, MOVE WITH OPTIONAL SPECIFICATIONS uses the key and address-space control in the current PSW to access both the first and second operands.
  5. In the MVCDK, MVCK, MVCP, MVCS, and MVCSK instructions, one operand is accessed using an implied key from the PSW, and the

other operand is accessed using a specified key in a register. In the problem state, only the specified key is checked for validity in the PSW-key mask (PKM).

When MVCOS is executed in the problem state, the access keys for the first and second operands are both checked for validity in the PKM, regardless of whether the keys are implied or specified.

## MOVE WITH SOURCE KEY

MVCSK	$D_1(B_1), D_2(B_2)$	[SSE]
'E50E'	$B_1$	$D_1$

The first operand is replaced by the second operand. The accesses to the source-operand location are performed by using the key specified in general register 1, and the accesses to the destination-operand location are performed by using the PSW key.

The first and second operands are of the same length, which is specified by bits 56-63 of general register 0. Bits 0-55 of general register 0 are ignored.

Bits 56-59 of general register 1 are used as the specified access key. Bits 0-55 and 60-63 of general register 1 are ignored.

The contents of general registers 0 and 1 are shown in Figure 10-32 on page 10-61.

GR0		L
	0	56
GR1		Key
	0	56

*Figure 10-32. Register Contents of MOVE WITH SOURCE KEY*

L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

The fetch accesses to the second-operand location are performed by using the key specified in general register 1, and the store accesses to the first-operand location are performed by using the PSW key.

Each of the operands is processed left to right. When the operands overlap destructively in real storage, the results in the first-operand location are unpredictable. Except for this unpredictability in the case of destructive overlap, the storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

## Special Conditions

In the problem state, the operation is performed only if the access key specified in general register 1 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)

### Programming Notes:

1. When data is to be moved alternately in both directions between two storage areas that are fetch protected by means of different keys, then MOVE WITH SOURCE KEY and MOVE WITH DESTINATION KEY can be used while leaving the PSW key unchanged; and this may be, on most models, significantly faster than using MOVE WITH KEY along with SET PSW KEY FROM ADDRESS to change the PSW key.
2. MOVE WITH SOURCE KEY and MOVE WITH DESTINATION KEY should be used only when movement is between storage areas having different keys. The performance of these instructions on most models may be significantly slower than that of the MOVE (MVC) instruction.
3. MOVE WITH SOURCE KEY or MOVE WITH DESTINATION KEY can be used in a loop to move a variable number of bytes as shown in the following example. In the example, the specified access key, the first-operand address, the second-operand address, and the length of each operand are assumed to be in general registers 1-4, respectively, at the beginning of the example. The length of each operand is treated as a

32-bit signed value, and a negative value is treated as zero.

	LTR	4,4
	BC	12,END
	AHI	4,-256
	BC	12,LAST
	LA	0,255

## PAGE IN

PGIN R<sub>1</sub>,R<sub>2</sub> [RRE]

'B22E'		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

A page-in operation is performed which transfers a 4K-byte block to the real-storage location designated by general register R<sub>1</sub> from the expanded-storage block designated by general register R<sub>2</sub>.

Bits 32-63 of general register R<sub>2</sub> are a 32-bit unsigned binary integer called the expanded-storage-block number. This number designates the 4K-byte block of expanded storage which is to be transferred. If the expanded-storage-block number designates an inaccessible block in expanded storage, condition code 3 is set.

The contents of general register R<sub>1</sub> are a real address which designates a 4K-byte block in main storage. In the 24-bit-addressing mode, bits 40-51 designate the block, and bits 0-39 are ignored. In the 31-bit-addressing mode, bits 33-51 designate the block, and bits 0-32 are ignored. In the 64-bit-addressing mode, bits 0-51 designate the block. In all modes, bits 52-63 of the address are ignored.

Because it is a real address, the address designating the main-storage block is not subject to dynamic address translation. PAGE IN is not subject to key-controlled storage protection, but low-address protection does apply. PAGE IN is not subject to program-event recording for storage alteration.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

If the page-in operation is completed with no errors, condition code 0 is set.

If the page-in operation encounters an expanded-storage data error, condition code 1 is set. For an expanded-storage data-error condition, the contents of the entire 4K-byte block in real storage is unpredictable, but this condition does not result in the generation of invalid checking-block codes in real storage.

If the expanded-storage block is not available, that is, the block is not provided or is not currently in the configuration, then condition code 3 is set, and no other action is taken.

### **Operation of PAGE IN in a Multiple-CPU Configuration**

The accesses to main storage and to expanded storage by PAGE IN are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

See also the description under PAGE OUT.

#### **Resulting Condition Code:**

- 0 Page-in operation completed
- 1 Expanded-storage data error
- 2 --
- 3 Expanded-storage block not available

#### **Program Exceptions:**

- Addressing (block designated by general register R<sub>1</sub>)
- Operation (if the expanded-storage facility is not installed)
- Privileged operation
- Protection (block designated by general register R<sub>1</sub>; low-address protection)

## **PAGE OUT**

PGOUT	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B22F'		R <sub>1</sub> R <sub>2</sub>

A page-out operation is performed which transfers a 4K-byte block from the real-storage location designated by general register R<sub>1</sub> to the expanded-storage block designated by general register R<sub>2</sub>.

Bits 32-63 of general register R<sub>2</sub> are a 32-bit unsigned binary integer called the expanded-storage-block number. This number designates the 4K-byte block of expanded storage which is to be replaced. If the expanded-storage-block number designates an inaccessible block in expanded storage, condition code 3 is set.

The contents of general register R<sub>1</sub> are a real address which designates a 4K-byte block in main storage. In the 24-bit-addressing mode, bits 40-51 designate the block, and bits 0-39 are ignored. In the 31-bit-addressing mode, bits 33-51 designate the block, and bits 0-32 is ignored. In the 64-bit-addressing mode, bits 0-51 designate the block. In all modes, bits 52-63 of the address are ignored.

Because it is a real address, the address designating the main-storage block is not subject to dynamic address translation. PAGE OUT is not subject to key-controlled protection.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

Depending on the model, after the data has been written to the expanded-storage block, a read-back-check operation may be performed to determine whether the data was written correctly. If the read-back-check operation determines that the data has been written correctly, condition code 0 is set. If the read-back-check operation encounters an expanded-storage data error, condition code 1 is set.

Most models do not perform the read-back-check operation, and, after the page-out operation is completed, condition code 0 is set.

Regardless of whether condition code 0 or condition code 1 is set, the entire 4K-byte block is written. Errors, if any, in the block after the block is written are

preserved. Thus, if a subsequent execution of PAGE IN addresses the same expanded-storage block, the expanded-storage data error will be detected and condition code 1 will be indicated.

If the expanded-storage block is not available, that is, the block is not provided or is not currently in the configuration, then condition code 3 is set, and no other action is taken.

#### **Operation of PAGE OUT in a Multiple-CPU Configuration**

The accesses to main storage and to expanded storage by PAGE OUT are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

If two or more CPUs issue PAGE IN or PAGE OUT instructions at approximately the same instant in time, depending on the model, the operations may be performed one at a time, or the operations may be performed concurrently. Concurrent operation may occur even if the instructions address the same expanded-storage block.

When two or more PAGE OUT instructions addressing the same expanded-storage block are executed concurrently, the resulting values in the expanded-storage block for each group of bytes transferred may be from any of the instructions being executed simultaneously. The number of bytes transferred as a group depends on the model.

Similarly, for concurrent execution of a PAGE IN and a PAGE OUT instruction for the same expanded-storage block, the resulting values for each group of bytes transferred as a result of the execution of the PAGE IN instruction may be either the old or new values from the expanded-storage block.

Concurrent operation of paging instructions does not result in expanded-storage data errors.

#### **Resulting Condition Code:**

- 0 Page-out operation completed
- 1 Expanded-storage data error
- 2 --
- 3 Expanded-storage block not available

#### **Program Exceptions:**

- Addressing (block designated by general register R<sub>1</sub>)
- Operation (if the expanded-storage facility is not installed)
- Privileged operation

## **PERFORM FRAME MANAGEMENT FUNCTION**

PFMF	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B9AF'	R <sub>1</sub> R <sub>2</sub>	0 16 24 28 31

Subject to the controls in the first-operand register, a frame-management function is performed for the storage frame designated by the second-operand address.

The contents of general register R<sub>1</sub> are as follows:

**Frame-management function indications:** Bit positions 44-47 of general register R<sub>1</sub> contain the frame-management function indications (FMFI), as follows:

**Reserved:** Bits 44 and 45 are reserved and must contain zeros; otherwise, a specification exception is recognized.

**Set-Key Control (SK):** Bit 46 controls whether the storage key for each 4K-byte block in the frame is set from bits 56-62 of general register R<sub>1</sub>. When the SK control is zero, the keys are not set; when the SK control is one, the keys are set.

**Clear-Frame Control (CF):** Bit 47 controls whether the frame is set to zeros. When the CF control is zero, no clearing operation is performed. When the CF control is one, the frame is cleared to zeros.

**Usage Indication (UI):** Bit position 48 of general register R<sub>1</sub> contains the usage indication (UI). When bit 48 is zero, it indicates that the program does not anticipate immediate usage of the frame. When bit 48 is one, it indicates that program anticipates usage of the frame in the near future.

**Frame-Size Code (FSC):** Bits 49-51 of general register R<sub>1</sub> contain the frame-size code (FSC), as follows:

FSC	Meaning
0	4K-byte frame
1	1M-byte frame
2-7	Reserved

**Reference-Bit Update Mask (MR):** When the set-key control, bit 46 of general register R<sub>1</sub>, is one, bit 53 of general register R<sub>1</sub> controls whether updates to the reference bit in the storage key may be bypassed, as described below.

**Change-Bit Update Mask (MC):** When the set-key control, bit 46 of general register R<sub>1</sub>, is one, bit 54 of general register R<sub>1</sub> controls whether updates to the change bit in the storage key may be bypassed.

The handling of the MR and MC bits is identical to the handling of the corresponding bits of the M<sub>3</sub> field of the SET STORAGE KEY EXTENDED instruction (described on page 10-114), except that general register R<sub>1</sub> is not updated with the contents of the previous key, and the condition code is not changed.

**Key:** When the set-key control, bit 46 of general register R<sub>1</sub>, is one, bits 56-62 of the register contain the storage key to be set for each 4K-byte block in the frame, with the access-protection bits, fetch-protection bit, reference bit, and change bit in bit positions 56-59, 60, 61, and 62, respectively.

General register R<sub>2</sub> contains the real or absolute address of the storage frame upon which the frame-management function is to be performed. When the frame-size code designates a 4K-byte block, the second-operand address is real; when the frame-size code designates a 1M-byte block the second-operand address is absolute. The handling of the address in general register R<sub>2</sub> depends on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-51 of the register, with 12 rightmost zeros appended, are the address, and bits 0-39 and 52-63 in the register are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of the register, with 12 rightmost zeros appended, are the address, and bits 0-32 and 52-63 in the register are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of the register, with 12 rightmost zeros appended, are the address, and bits 52-63 in the register are ignored.

The contents of the registers just described are shown in Figure 10-33 on page 10-66.

When the frame-size code is 0, the specified frame-management functions are performed for the 4K-byte frame specified by the second operand. General register R<sub>2</sub> is unmodified in this case.

When the frame-size code is 1, the specified frame-management functions are performed for one or more 4K-byte blocks within the 1M-byte frame, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 1M-byte boundary. In this case, PERFORM FRAME MANAGEMENT FUNCTION is interruptible, and processing is as follows:

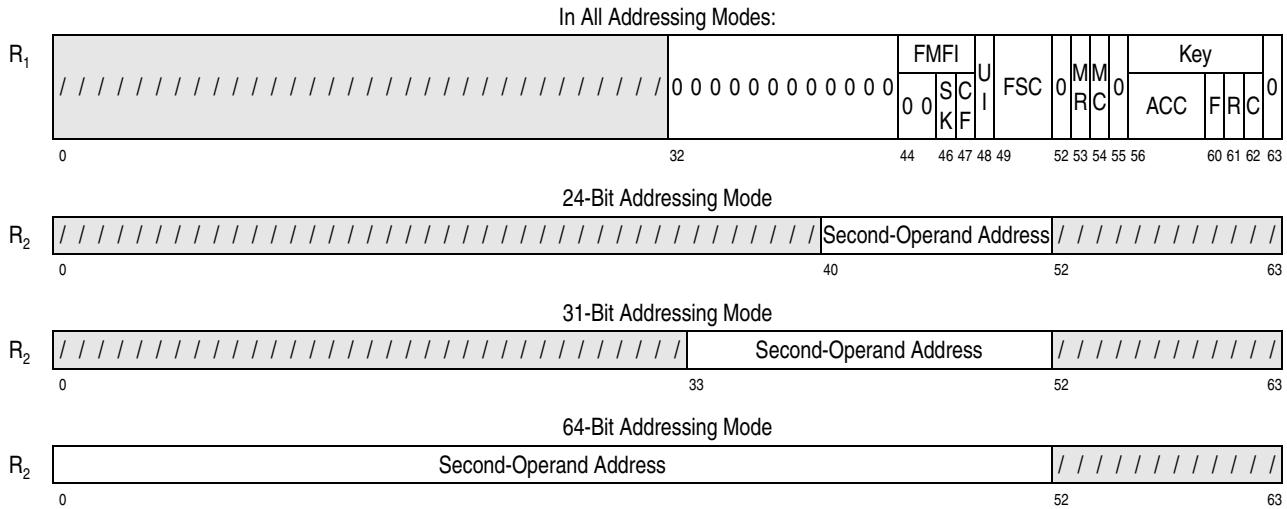

- When an interruption occurs (other than one that follows termination), the second-operand address in general register R<sub>2</sub> is updated by the number of 4K-byte blocks processed, so the instruction, when reexecuted, resumes at the point of interruption.
- When the instruction completes without interruption, the second-operand address in general register R<sub>2</sub> is updated to the next 1M-byte boundary.

When the frame-size code is 1, the following also applies:

- In the 24-bit addressing mode, bit positions 32-39 of general register R<sub>2</sub> are set to zeros.
- In the 31-bit addressing mode, bit position 32 of general register R<sub>2</sub> is set to zero.
- In either the 24-bit or 31-bit addressing mode, bits 0-31 of general register R<sub>2</sub> are unchanged.

When the clear-frame control is one, references to main storage within the second operand are not necessarily single-access references and are not necessarily performed in a left-to-right direction as observed by other CPUs and by channel programs. The clear operation is not subject to key-controlled protection; however low-address protection applies regardless of whether the frame-size code designates a 4 K-byte or 1 M-byte frame (that is, regardless of whether the second-operand address is real or absolute, respectively).

When the storage-key control is one, the operation for each 4K-byte block is similar to that described in “SET STORAGE KEY EXTENDED” on page 10-114,

## **Explanation:**

ACC	Access-protection bits of the storage key
C	Change bit of the storage key
CF	Clear-frame control
F	Fetch-protection bit of the storage key
FMFI	Frame-management function indication
FSC	Frame-size code
MC	Change-bit-update mask
MR	Reference-bit-update mask
R	Reference bit of the storage key
SK	Set-key control
UI	Usage indication

*Figure 10-33. Register Contents for PERFORM FRAME-MANAGEMENT FUNCTION*

except that when the keys for multiple blocks are set, the condition code and the contents of general register R<sub>1</sub> are unchanged. A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed, except that when the seven bits of all storage keys to be set are the same as bits 56-62 of general register R<sub>1</sub>, or when the MR and MC bits allow all the storage keys to remain unchanged, it is unpredictable whether the serialization and checkpoint-synchronization operations are performed after the operation completes. See “SET STORAGE KEY EXTENDED” on page 10-114 for details on the cases where setting of the key may be bypassed.

It is unpredictable whether the clear-frame or the set-key operation is performed first when both of the respective controls are one. When both the clear-frame and set-key controls are one, and either the MR or MC bit is also one, and the clear operation is performed first, the storage key that is compared with

bits 56-62 of general register R<sub>1</sub> in the set-key operation is the key following the clear operation (that is, both the R and C bits will have been set to one by the clear operation). Provided that there is no other access to the storage by other CPUs or the channel subsystem, the final results of the instruction reflect the specified key value, including the specified R and C values when MR and MC are zero.

### **Special Conditions**

A specification exception is recognized and the operation is suppressed for any of the following conditions:

- Bits 32-45, 52, 55, or 63 of general register  $R_1$  are not zero.
  - The frame-size code specifies a reserved value.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (store, low-address-protection only, operand 2, when the clear-frame control is one)
- Addressing (operand 2)
- Operation (enhanced-DAT facility not installed)
- Privileged operation
- Specification

## PERFORM TIMING FACILITY FUNCTION

PTFF [E]  
  
 0 15

A timing facility function specified by the function code in general register 0 is performed. The condition code is set to indicate the outcome of the function. General register 1 contains the address of a parameter block in storage. PTFF query functions place information in the parameter block; PTFF control functions use information obtained from the parameter block.

As observed by other CPUs and channel programs, references to the parameter block may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Bit positions 57-63 of general register 0 contain the function code. Figure 10-35 on page 10-68 shows the assigned function codes. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

Figure 10-34 on page 10-67 shows the contents of the general registers just described.

All Addressing Modes		
GR0		FC
0		56 57 63
24-Bit Addressing Mode		
GR1		Parameter-Block Address
0		40
31-Bit Addressing Mode		
GR1		Parameter-Block Address
0		33 63
64-Bit Addressing Mode		
GR1		Parameter-Block Address
0		63

Figure 10-34. General Register Assignment for PERFORM TIMING FACILITY FUNCTION

In the access-register mode, access register 1 specifies the address space containing the parameter block.

The function codes for PERFORM TIMING FACILITY FUNCTION are as follows.

Code		Function	Parm. Block Size (bytes)	Action
Hex	Dec			
00	0	PTFF-QAF	16	P
01	1	PTFF-QTO	32	P
02	2	PTFF-QSI	56	P
03	3	PTFF-QPT	8	P
40	64	PTFF-ATO	8	Sb
41	65	PTFF-STO	8	Sh
42	66	PTFF-SFS	4	Sb
43	67	PTFF-SGS	4	Sb

**Explanation:**

P Available in problem state at all levels of CPU execution (basic-machine, logical-partition, and virtual-machine).  
Sb Available in supervisor state at the basic-machine level.  
Sh Available in supervisor state at the basic-machine level. May be available to the supervisor-state program at the logical-partition and virtual-machine levels, subject to emulation by the hypervisor.

Figure 10-35. Function Codes for PERFORM TIMING FACILITY FUNCTION

All other function codes are unassigned.

The PTFF-QAF (Query Available Functions) function provides the means of indicating the availability of the other functions. The PTFF-QAF function indicates whether the function is installed for a program running in supervisor state at the basic-machine level.

### PTFF-QAF (Query Available Functions)

The parameter block used for the function has the following format:

Hex	Dec	0      31	pb.w1
00	0	Status Bits 0-31	pb.w1
04	4	Status Bits 32-63	pb.w2
08	8	Status Bits 64-95	pb.w3
0C	12	Status Bits 95-127	pb.w4

Figure 10-36. Parameter Block for PTFF-QAF (Query Available Functions)

A 128-bit field is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PTFF instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed. Bits 0-3 of pb.w1 are set to ones, as these bits represent function codes 0-3, which are currently assigned to query functions. Bits 4-31 of pb.w1 are reserved for additional query functions. Bits 0-3 of pb.w3 are set to ones, as these bits represent function codes 64-67, which are currently assigned to control functions. Bits 4-31 of pb.w3 are reserved for additional control functions. Parameter block words pb.w2 and pb.w4 are reserved for future extensions.

### PTFF-QTO (Query TOD Offset)

The parameter block used for the function has the following format:

Hex	Dec	0      31	
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	TOD Offset (0:31)	pb.d
0C	12	TOD Offset (32:63)	
10	16	Logical TOD Offset (0:31)	pb.dl
14	20	Logical TOD Offset (32:63)	
18	24	TOD Epoch Difference (0:31)	pb.ed
1C	28	TOD Epoch Difference (32:63)	

Figure 10-37. Parameter Block for PTFF-QTO (Query TOD Offset)

The 64-bit physical-clock value returned (pb.Tu) is the value of the physical clock at the most recent TOD-offset-update event.

The 64-bit TOD-offset value returned (pb.d) indicates the value of the TOD-offset (d). This is the current value being added to Tr (the physical clock) to obtain Tb (the basic-machine TOD clock); that is,  $Tb = Tr + pb.d$ .

The 64-bit logical-TOD-offset value returned (pb.dl) indicates the current value being added to Tr (the physical clock) to obtain Tc (the logical TOD clock for the current level of CPU execution); that is,  $Tc = Tr + pb.dl$ . Thus, when executed at the basic-machine level,  $pb.dl = pb.d = d$ ; when executed at the logical-partition level, the  $Tp-Tb$  epoch difference ( $D_p$ ) is added, resulting in  $pb.dl = d + D_p$ ; and when executed at the virtual-machine level, the  $Tv-Tp$  epoch difference ( $D_v$ ) is also added, resulting in  $pb.dl = d + D_v$ .

$D_p + D_v$ . Carries, if any, out of bit position 0 are ignored in the addition for each of these equations.

The 64-bit TOD epoch difference value returned (pb.ed) is the TOD epoch difference for the current level of CPU execution. When executed at the basic-machine level, this value is zero; when executed at the logical-partition level, this value is the  $T_p - T_b$  epoch difference ( $D_p$ ); when executed at the virtual-machine level, this value is the  $T_v - T_p$  epoch difference ( $D_v$ ).

### PTFF-QSI (Query Steering Information)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	Old Episode Start Time (0:31)	
0C	12	Old Episode Start Time (32:63)	
10	16	Old Episode Base Offset (0:31)	
14	20	Old Episode Base Offset (32:63)	
18	24	Old Episode Fine-Steering Rate	
1C	28	Old Episode Gross-Steering Rate	
20	32	New Episode Start Time (0:31)	
24	36	New Episode Start Time (32:63)	
28	40	New Episode Base Offset (0:31)	
2C	44	New Episode Base Offset (32:63)	
30	48	New Episode Fine-Steering Rate	
34	52	New Episode Gross-Steering Rate	
		0 31	

Figure 10-38. Parameter Block for PTFF-QSI (Query Steering Information)

The 64-bit physical-clock value returned (pb.Tu) is the value of the physical clock at the most recent TOD-offset-update event. The remaining fields are the values of the old-episode and new-episode registers.

### PTFF-QPT (Query Physical Clock)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tr
04	4	Physical Clock (32:63)	
		0 31	

Figure 10-39. Parameter Block for PTFF-QPT (Query Physical Clock)

The 64-bit physical-clock value returned (pb.Tr) is the current value of the physical clock. Zeros are stored for the rightmost bit positions that are not provided by the physical clock. When the clock is running, two executions of PTFF-QPT, either on the same or different CPUs, do not necessarily return different values of the clock.

### PTFF-ATO (Adjust TOD Offset)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	TOD Offset Adjustment (0:31)	pb.a
04	4	TOD Offset Adjustment (32:63)	
		0 31	

Figure 10-40. Parameter Block for PTFF-ATO (Adjust TOD Offset)

The 64-bit value (pb.a) from the parameter block, treated as an unsigned-binary value, is added to the base offset of the next episode. A carry if any, out of bit position 0 is ignored in this addition. The effect is not immediate, but is scheduled to coincide with the next TOD-offset-update event.

If the next episode has already been scheduled, and has not yet become active, then the sum of pb.a and new.b replaces new.b and no other action is taken.

If the next episode has not been scheduled (that is, the new-episode registers are the current episode), then the new-episode registers are saved in the old-episode registers and a new episode is scheduled (thus, making the old-episode registers the current episode). The new-episode start time (new.s) is set to the value the physical clock will have at the next TOD-offset-update event and the new-episode base offset (new.b) is set to the sum of pb.a and the value

the TOD-offset would have had at that same instant, computed using the current steering parameters.

The steering rate is not changed by this function, if a new episode is scheduled, the new-episode fine-steering and gross-steering rates are the same as the current values.

Execution of the adjust-TOD-offset function is interlocked such that the entire contents of the TOD-offset register appear to be updated concurrently and simultaneously as observed by all CPUs in the configuration. However, accesses to the logical TOD clocks (basic-machine TOD clock, logical-partition TOD clock, and virtual-machine TOD clock) by CPUs in the configuration are not artificially delayed; thus, addition of a large unsigned adjustment value may have the effect of a negative change and may cause the logical TOD clocks to appear to step backwards.

### **PTFF-STO (Set TOD Offset)**

The parameter block used for the function has the following format:

Hex	Dec		
00	0	New TOD Offset (0:31)	pb.d
04	4	New TOD Offset (32:63)	

0      31

Figure 10-41. Parameter Block for PTFF-STO (Set TOD Offset)

The 64-bit value (pb.d) from the parameter block replaces the TOD offset.

When issued at the basic-machine level, the effect is not immediate, but is scheduled to coincide with the next TOD-offset-update event.

If the next episode has already been scheduled, and has not yet become active, then pb.d replaces new.b and no other action is taken.

If the next episode has not been scheduled (that is, the new-episode registers are the current episode), then the new-episode registers are saved in the old-episode registers and a new episode is scheduled (thus, making the old-episode registers the current episode). The new-episode start time (new.s) is set to the value the physical clock will have at the next TOD-offset-update event and the new-episode base offset (new.b) is set to the value of pb.d.

The steering rate is not changed by this function, if a new episode is scheduled, the new-episode fine-steering and gross-steering rates are the same as the current values.

When issued at the logical-partition or virtual-machine level, the function may be simulated by the hypervisor and operates on the TOD epoch difference for the current level of CPU execution (Dp or Dv, respectively); no new episode is scheduled and the change takes effect immediately.

Execution of the set-TOD-offset function is interlocked such that the entire contents of the TOD-offset register appear to be updated concurrently and simultaneously as observed by all CPUs in the configuration. However, accesses to the logical TOD clocks (basic-machine TOD clock, logical-partition TOD clock, and virtual-machine TOD clock) by CPUs in the configuration are not artificially delayed; thus, replacement of the TOD offset by a smaller value may cause the logical TOD clocks to appear to step backwards.

### **PTFF-SFS (Set Fine-Steering Rate)**

The parameter block used for the function has the following format:

Hex	Dec		
00	0	New Fine-Steering Rate	pb.f

0      31

Figure 10-42. Parameter Block for PTFF-SFS (Set Fine-Steering Rate)

The 32-bit value (pb.f) from the parameter block becomes the fine-steering rate for the next episode. The effect is not immediate, but is scheduled to coincide with the next TOD-offset-update event.

If the next episode has already been scheduled, and has not yet become active, then pb.f replaces new.f and no other action is taken.

If the next episode has not been scheduled (that is, the new-episode registers are the current episode), then the new-episode registers are saved in the old-episode registers and a new episode is scheduled (thus, making the old-episode registers the current episode). The new-episode start time (new.s) is set to the value the physical clock will have at the next TOD-offset-update event and the new-episode base offset (new.b) is set to the value the TOD-offset will

have at that same instant, computed using the current steering parameters. The new-episode fine-steering rate (new.f) is set to pb.f and the new-episode gross-steering rate is the same as the current value.

When the new episode takes effect, accesses to the logical TOD clocks by CPUs in the configuration are interlocked to ensure that the logical TOD clocks appear to be unique and monotonically increasing as observed by all programs.

### PTFF-SGS (Set Gross-Steering Rate)

The parameter block used for the function has the following format:

Hex	Dec	
00	0	New Gross-Steering Rate      pb.g 0    31

Figure 10-43. Parameter Block for PTFF-SGS (Set Gross-Steering Rate)

The 32-bit value (pb.g) from the parameter block becomes the gross-steering rate for the next episode. The effect is not immediate, but is scheduled to coincide with the next TOD-offset-update event.

If the next episode has already been scheduled, and has not yet become active, then pb.g replaces new.g and no other action is taken.

If the next episode has not been scheduled (that is, the new-episode registers are the current episode), then the new-episode registers are saved in the old-episode registers and a new episode is scheduled (thus, making the old-episode registers the current episode). The new-episode start time (new.s) is set to the value the physical clock will have at the next TOD-offset-update event and the new-episode base offset (new.b) is set to the value the TOD-offset will have at that same instant, computed using the current steering parameters. The new-episode gross-

steering rate (new.g) is set to pb.g and the new-episode fine-steering rate is the same as the current value.

When the new episode takes effect, accesses to the logical TOD clocks by CPUs in the configuration are interlocked to ensure that the logical TOD clocks appear to be unique and monotonically increasing as observed by all programs.

### Special Conditions

The priority of execution for the PTFF instruction is shown in Figure 10-44.

A privileged operation exception is recognized if a PTFF control function is issued in the problem state.

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstantiated function code.

### Resulting Condition Code:

- |   |                                  |
|---|----------------------------------|
| 0 | Requested function performed     |
| 1 | --                               |
| 2 | --                               |
| 3 | Requested function not available |

### Program Exceptions:

- Access (fetch, parameter block for control functions; store, parameter block for query functions)
- Operation (if the PERFORM TIMING FACILITY FUNCTION instruction is not installed)
- Privileged operation (attempt to execute a PTFF control function in the problem state)
- Specification

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.	Operation exception.
8.	Specification exception due to bit 56 of general register 0 being one or bits 57-63 of general register 0 specifying an unassigned or uninstalled function code.
9.	Privileged-operation exception due to attempt to issue PTFF control function in the problem state.
10.	Condition code 3 due to a control function not available in supervisor state.
11.	Access exceptions for an access to the parameter block.
12.	Condition code 0 indicating successful completion.

Figure 10-44. Priority of Execution: PERFORM TIMING FACILITY FUNCTION (PTFF)

#### Programming Notes:

1. The status bits returned by the PTFF-QAF function indicate the PTFF functions which are installed and available for a program running in supervisor state at the basic-machine level. Since all installed PTFF query functions are available in both the problem state and supervisor state at all levels of CPU execution, these status bits can be used directly by any program to determine which PTFF query functions are available. PTFF control functions are never available to a program running in problem state. Condition code 3 is set when a particular PTFF control function is issued and the function is installed but is not available in that state or at that level of CPU execution. Thus, the status bits for PTFF control functions indicate whether it is safe to issue a particular PTFF control function without the danger of a specification exception.
2. The physical time (pb.Tu) returned in the parameter block for PTFF-QTO and PTFF-QSI is the current value of the physical clock, but with zeroes in positions to the right of the bit position incremented concurrently with each TOD-offset-update event. This value is not necessarily unique. The same value may be returned if the PTFF instruction is issued multiple times on the

same CPU or issued at approximately the same time on different CPUs.

3. The 64-bit value of the physical clock at the most recent TOD-offset-update event (pb.Tu) returned by PTFF-QTO and PTFF-QSI may be used by the program to ensure that all events during a short routine occurred with no intervening TOD-offset-update events. This can be accomplished by issuing one of these queries at the beginning of the routine and the other at the end and reiterating if the value of pb.Tu before and the value of pb.Tu after are different.
4. Given information from PTFF-QTO, the following equations show the relationship between Tr (the physical clock), Tb (basic-machine TOD clock), and Tc (logical TOD clock for the current level of CPU execution):

$$Tb = Tr + pb.d$$

$$Tc = Tr + pb.dl$$

These equations hold only for the time between two TOD-offset-update events. The information from PTFF-QSI can be used to extend this relationship for the entire time span of two episodes, beginning with the old-episode start time (pb.old.s) through the new episode and continuing on to that instant in the future when a subsequent episode takes effect.

5. For PTFF-QTO (Query TOD Offset) and PTFF-QSI (Query Steering Information), the 64-bit physical-clock value returned (pb.Tu) is the value of the physical clock at the most recent TOD-offset-update event. This is the current value of the physical clock, but with zeroes in positions to the right of the bit position incremented concurrently with each TOD-offset-update event. The program can use this value to determine the time span over which the various offsets returned by Query TOD Offset can be used without any error. For Query Steering Information, pb.Tu can be used to determine whether the machine is operating in the old or new episode. When pb.new.s ≤ pb.Tu, the machine is operating in the new episode, and none of the information returned by the query has changed since the most recent TOD-offset-update event. When pb.new.s > Pb.Tr, the machine is operating in the old episode, a new episode has been scheduled and has not yet taken effect. The program should avoid any dependency on the new episode values returned

in this case, as it is possible the values may change again before the new episode takes effect.

6. Two or more executions of PTFF-QPT within a short period of time, either on the same or different CPUs, do not appear to step backwards, but are not necessarily unique. Thus, it is not always possible to use the values to determine the sequence of execution.
7. The Network Time Protocol (NTP) is used extensively in the internet. A description of NTP may be found in Request for Comments (RFC) 1305. Figure 10-46 on page 10-74 shows the value of the TOD clock and NTP timestamp for 00:00:00

(0 am), UTC time, for several dates: January 1, 1900, January 1, 1972, and for that instant in time just after each of the 23 leap seconds that have occurred through January, 2006. Each of these leap seconds was inserted in the UTC time scale beginning at 23:59:60 UTC of the day previous to the one listed and ending at 00:00:00 UTC of the day listed. Also included are values for the beginning of each year since the most recent leap second. Figure 10-45 on page 10-73 shows the values of the TOD clock and NTP timestamp for those instants just after the leftmost bit of one or the other has changed. For instants in the future, the number of leap seconds must be applied and this value is not yet known.

YYYY	MM	DD	hh mm ss	TOD Clock (Hex)	NTP Timestamp (Hex)
1968	01	20	03:14:08.000000	7A12 0000 0000 0000	8000 0000 0000 0000
1971	05	11	11:56:53.685248	8000 0000 0000 0000	8637 BD05 AF6C 69B5*
2036	02	07	06:28:16.000000	F424 0000 0000 0000+	0000 0000 0000 0000
2042	09	17	23:53:47.370496-	0000 0000 0000 0000	0C6F 7A0B 5ED8 D36B*-

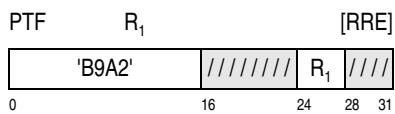

**Explanation:**

- \* Value is not exact.
- + Leap seconds must be added to this value.
- Leap seconds must be subtracted from this value.

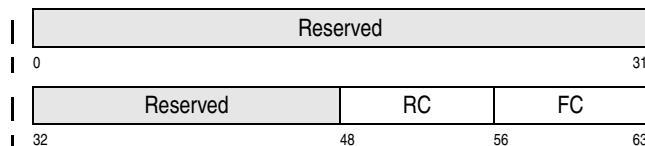

Figure 10-45. TOD Clock and NTP Timestamps When a Leftmost Bit Changes

Year	Month	Day	Leap Sec.	TOD Clock (Hex)	NTP Timestamp (Hex)

Figure 10-46. TOD Clock and NTP Timestamps

**PERFORM TOPOLOGY FUNCTION**

The contents of general register R<sub>1</sub> specify a function code in bit positions 56-63, as illustrated in Figure 10-47.

Figure 10-47. General-Register R<sub>1</sub> Format

The defined function codes are as follows:

**FC      Meaning**

- 0      Request horizontal polarization.
- 1      Request vertical polarization.
- 2      Check topology-change status.

Undefined function codes in the range 0-255 are reserved for future extensions.

Upon completion, if condition code 2 is set, a reason code is stored in bit positions 48-55 of general register R<sub>1</sub>.

Bits 16-23 and 28-31 of the instruction are ignored.

### Operation of Function Codes 0 and 1

When no exceptional conditions are detected, a process is initiated to place all CPUs in the configuration into the polarization specified by the function code, and condition code 0 is set. Completion of the process is asynchronous with respect to execution of the instruction and may or may not be completed when execution of the instruction completes.

Execution completes with condition code 2, and the reason code is set, for any of the following reasons:

**RC      Reason**

- 0      No reason specified.
- 1      The configuration is already polarized as specified by the function code.
- 2      A topology change is already in process

### Operation of Function Code 2:

The topology-change-report-pending condition is checked. When a topology-change-report is not pending, condition code 0 is set. When a topology-change report is pending, condition code 1 is set.

A topology change is any alteration such that the contents of a SYSIB 15.1.2 would be different from the contents of the SYSIB 15.1.2 prior to the topology change.

A topology-change-report-pending condition is created when a topology-change process completes. A topology-change-report-pending condition is cleared for the configuration when any of the following is performed:

- Execution of PERFORM TOPOLOGY FUNCTION specifies function-code 2 that completes with condition code 1.
- STORE SYSTEM INFORMATION for SYSIB 15.1.2 is successfully executed by any CPU in the configuration.
- Subsystem reset is performed.

### Special Conditions

A specification exception is recognized for either of the following conditions:

- Bit positions 0-55 of general register R<sub>1</sub> are not zeros.
- An undefined function code is specified.

**Resulting Condition Code:** When the function code is 0 or 1, the condition code is set as follows:

- 0      Topology-change initiated
- 1      --
- 2      Request rejected
- 3      --

When the function code is 2, the condition code is set as follows:

- 0      Topology-change-report not pending
- 1      Topology-change report pending
- 2      --
- 3      --

### Program Exceptions:

- Operation (configuration-topology facility is not installed)
- Privileged operation
- Specification

**Programming Note:** Further information on configuration topology may be found in "SYSIB 15.1.2 (Configuration Topology)" on page 10-134.

## PROGRAM CALL

PC	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B218'	B <sub>2</sub>
		D <sub>2</sub>
	16	20
		31

A program-call number specified by the second-operand address is used in a two-level or three-level lookup to locate an entry-table entry (ETE). The program is authorized to use the ETE when the AND of the PSW-key mask in control register 3 and the authorization key mask in the ETE is nonzero or when the CPU is in the supervisor state.

When the PC-type bit, bit 128 of the ETE, is zero, an operation called basic PROGRAM CALL is performed. When the PC-type bit is one, an operation called stacking PROGRAM CALL is performed.

Basic PROGRAM CALL, in the 24-bit or 31-bit addressing mode, loads the basic-addressing-mode bit, bits 33-62 of the updated instruction address, and the problem-state bit from the PSW into bit positions 32-63 of general register 14, and it leaves bits 0-31 of this register unchanged. In the 64-bit addressing mode, bits 0-62 of the updated instruction address and the problem-state bit are placed in bit positions 0-63 of general register 14. In any addressing mode, the PSW-key mask and PASN are placed in bit positions 32-63 of general register 3, and bits 0-31 of this register remain unchanged.

Stacking PROGRAM CALL places the entire PSW contents, except with an unpredictable PER mask, and also the PSW-key mask, PASN, SASN, and EAX in a linkage-stack program-call state entry that it forms. A called-space identification, an indication of whether the resulting addressing mode is the 64-bit mode, the numeric part of the program-call number, and the contents of general registers 0-15 and access registers 0-15 also are placed in the state entry. If the ASN-and-LX-reuse facility is installed and enabled, the PASTEIN and SASTEIN also are placed in the state entry.

For basic PROGRAM CALL, the extended-addressing-mode bit, bit 31 of the PSW, must have the same value as the entry-extended-addressing-mode bit, bit 129 of the ETE; otherwise, a special-operation exception is recognized. Basic PROGRAM CALL does not change bit 31 of the PSW and, therefore, does not switch between a basic addressing mode (the 24-bit or 31-bit mode) and the extended addressing mode (the 64-bit mode). In the 24-bit or 31-bit addressing mode, basic PROGRAM CALL sets the basic-addressing-mode bit, bit 32 of the PSW, with the value of the entry-basic-addressing-mode bit, bit 32 of the ETE, and, thus, it may switch between the 24-bit and 31-bit addressing modes. In

the 64-bit addressing mode, bit 32 of the PSW remains unchanged.

Stacking PROGRAM CALL, when bit 129 of the ETE is zero, sets bit 31 of the PSW to zero and sets bit 32 of the PSW with the value of bit 32 of the ETE. When bit 129 of the ETE is one, stacking PROGRAM CALL sets bits 31 and 32 of the PSW to one. Thus, stacking PROGRAM CALL can set the 24-bit, 31-bit, or 64-bit addressing mode.

When the resulting addressing mode is the 24-bit or 31-bit mode, both basic and stacking PROGRAM CALL place bits 33-62 of the entry instruction address in the ETE, which are bits 33-62 of the ETE, with 33 leftmost and one rightmost zeros appended, in bit positions 64-127 of the PSW as the new instruction address, and they place the entry-problem-state bit, bit 63 of the ETE, in bit position 15 of the PSW as the new problem-state bit. Bits 32-63 of the entry parameter in the ETE are placed in bit positions 32-63 of general register 4, and bits 0-31 of this register remain unchanged.

When the resulting addressing mode is the 64-bit mode, both basic and stacking PROGRAM CALL place bits 0-62 of the entry instruction address, bits 0-62 of the ETE, with one rightmost zero appended, in bit positions 64-127 of the PSW, and they place bit 63 of the ETE in bit position 15 of the PSW. Bits 0-63 of the entry parameter in the ETE are placed in general register 4.

Basic PROGRAM CALL ORs the entry key mask from the ETE into the PSW-key mask in control register 3. Stacking PROGRAM CALL does the same, or it replaces the PSW-key mask with the entry key mask, as determined by the PSW-key-mask control in the ETE.

Stacking PROGRAM CALL optionally replaces the PSW key in the PSW and the EAX in control register 8 from the ETE, and it sets the address-space-control bits in the PSW, as determined by control bits in the ETE.

The ETE causes a space-switching operation to occur if it contains a nonzero ASN. When the ETE contains a zero ASN, the operation is called PROGRAM CALL to current primary (PC-cp); when the ETE contains a nonzero ASN, the operation is called PROGRAM CALL with space switching (PC-ss). When space switching is specified, the new PASN is loaded into control register 4 from the ETE, and a

new primary-ASTE origin (PASTEO) is loaded into control register 5, also from the ETE. From the PASTE, a new primary ASCE (PASCE) and AX are loaded into control registers 1 and 4, respectively. If ASN-and-LX reuse is enabled, a new primary ASTE instance number (PASTEIN) is loaded into control register 4, also from the PASTE.

In both PC-cp and PC-ss, the SASN and secondary ASCE (SASCE) are set equal to the original PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, the secondary ASTE instance number (SASTEIN) in control register 3 is set equal to the original PASTEIN. However, the space-switching stacking PROGRAM CALL operation may instead set the SASN and SASCE equal to the new PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, set the SASTEIN equal to the new PASTEIN, as determined by a control bit in the ETE.

In a PC-ss to the base space of the dispatchable unit when the dispatchable unit is subspace active, bits 0-55 and 58-63 of the new PASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This occurs before the possible setting of the SASCE equal to the PASCE.

### PROGRAM CALL PC-Number Translation

The second-operand address is not used to address data; instead, the rightmost 20 or 32 bits of the address are used as a PC number divided into two fields: a linkage index (LX) and an entry index (EX). The entry index is always the rightmost eight bits of the PC number. When the ASN-and-LX-reuse is not installed or is not enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the PC number is 20 bits, and the leftmost 12 bits of the number are the linkage index. In this case, the second-operand address has the following format:

Second-Operand Address when ASN-and-LX Reuse Is Not Enabled

0	LX	EX	31
32	44	56	63

Bit 44 of the effective address has no special meaning and may be zero or one.

When the ASN-and-LX-reuse facility is installed and enabled, referred to simply by saying that ASN-and-LX reuse is enabled, the linkage index is further divided into a linkage first index (LFX) and a linkage second index (LSX). The linkage second index is always the five bits immediately on the left of the entry index. The size and format of the linkage first index depend on whether the PC number is 20 bits or 32 bits, which in turn depends on whether bit 44 of the second-operand address is zero or one, respectively. In these cases, the second-operand address has the following formats:

Second-Operand Address when ASN-and-LX Reuse Is Enabled and Bit 44 Is Zero

0	LX			31
	LFX			
32	44 45	51	56	63

Second-Operand Address when ASN-and-LX Reuse Is Enabled and Bit 44 Is One

0	LX			31
	LFX			
32	44 45	51	56	63

When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is zero, the PC number is 20 bits, and the linkage first index is bits 44-50, or bits 45-50 (LFX2) with a zero appended on the left. Thus, the linkage first index is seven bits of which the leftmost bit is always zero. When bit 44 is one, the PC number is 32 bits, and the linkage first index is bits 45-50 (LFX2) with bits 32-43 (LFX1) appended on the left, or 18 bits, and bit 44 is not a numeric part of the PC number. However, a linkage first table can contain at most 16,384 entries, and, therefore, the leftmost four bits of the linkage first index, bits 32-35 of the second-operand address, must always be zeros; otherwise, an LFX-translation exception is recognized.

**Linkage Index (LX):** When ASN-and-LX reuse is not enabled, bits 44-55 of the second-operand address are the linkage index and are used to select an entry from the linkage table designated by the linkage-table designation in the primary ASTE.

**Linkage First Index (LFX):** When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is zero, bits 44-50 of the second-operand address are the linkage first index. When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is one, bits 45-50 with bits 32-43 appended on the left are the linkage first index. In either case, the linkage first index is used to select an entry from the linkage first table designated by the linkage-first-table designation in the primary ASTE.

**Linkage Second Index (LSX):** When ASN-and-LX reuse is enabled, bits 51-55 of the second-operand address are the linkage second index and are used to select an entry from the linkage second table designated by the linkage-first-table entry.

**Entry Index (EX):** Bits 56-63 of the second-operand address are the entry index and are used to select an entry from the entry table designated by the linkage-table entry or the linkage-second-table entry.

When the PC number is 20 bits, bits 32-43 of the second-operand address are ignored. Bits 0-31 of the second-operand address are always ignored.

When ASN-and-LX reuse is enabled, the second word of the linkage-second-table entry used contains a linkage-second-table-entry sequence number (LSTESN). When this LSTESN is nonzero, it must be equal to an LSTESN specified in bit positions 0-31 of general register 15; otherwise, an LSTE-sequence exception is recognized. When ASN-and-LX reuse is not enabled (including when it is not installed) or the LSTESN in the linkage-second-table entry is zero, bits 0-31 of general register 15 are ignored.

The 32-byte entry-table entry (ETE) has the following format:

When Resulting Addressing Mode Is the 24-Bit or 31-Bit Mode

0	31
A	Entry Instruction Address P

32 33

When Resulting Addressing Mode Is the 64-Bit Mode

0	31
32	P 63

Authorization Key Mask	ASN
64	80 95
Entry Key Mask	
96	112 127
T G K M E C S EK	EEAX
128 131 136 140 144	159
ASTE Origin	
160	186 191
Entry Parameter (Part 1)	
192	223
Entry Parameter (Part 2)	
224	255

For basic PROGRAM CALL in the 24-bit or 31-bit addressing mode when bit 32 of the ETE (A) is zero (specifying the 24-bit mode), and for stacking PROGRAM CALL when bits 32 (A) and 129 (G) are zeros (specifying the 24-bit mode), bits 33-39 must be zeros; otherwise, a PC-translation-specification exception is recognized.

After the ETE has been fetched, if the current PSW specifies the problem state, the current PSW-key mask in control register 3 is tested against the AKM field in the ETE to determine whether the program is authorized to access this entry. The AKM and PSW-key mask are ANDed, and, if the result is zero, a privileged-operation exception is recognized. The PSW-key mask in control register 3 remains unchanged. When PROGRAM CALL is executed in the supervisor state, the AKM field is ignored.

If the result of the AND of the AKM and the PSW-key mask is not zero, or if the CPU is in the supervisor state, the execution of the instruction continues.

If bit 128 of the ETE (T) is zero, the basic PROGRAM CALL operation is specified. If bit 128 of the ETE is one, the stacking PROGRAM CALL operation is specified.

## Basic PROGRAM CALL

The following operations are performed when basic PROGRAM CALL is specified.

Bit 31 of the current PSW (the extended-addressing-mode bit) must equal bit 129 (G) of the ETE; otherwise, a special-operation exception is recognized.

In the 24-bit or 31-bit addressing mode, bits 97-126 of the PSW (bits 33-62 of the updated instruction address) are placed in bit positions 33-62 of general register 14, bit 32 of the PSW (the basic-addressing-mode bit) is placed in bit position 32 of the register, and bit 15 of the PSW (the problem-state bit) is placed in bit position 63 of the register. Bits 0-31 of the register remain unchanged.

In the 64-bit addressing mode, bits 64-126 of the PSW (bits 0-62 of the updated instruction address) are placed in bit positions 0-62 of general register 14, and bit 15 of the PSW (the problem-state bit) is placed in bit position 63 of the register.

In the 24-bit or 31-bit addressing mode, bits 32 and 33-62 of the ETE (A and the EIA), with a zero appended on the right of bits 33-62, are placed in PSW bit positions 32 and 97-127, respectively (the basic-addressing-mode bit and bits 33-63 of the instruction address). In the 64-bit addressing mode, bits 0-62 of the ETE, with a zero appended on the right, are placed in PSW bit positions 64-127 (the instruction address), and PSW bit 32 remains unchanged. In any addressing mode, bit 63 of the ETE (P) is placed in PSW bit position 15 (the problem-state bit).

The PSW-key mask, bits 32-47 of control register 3, is placed in bit positions 32-47 of general register 3, and the current PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of general register 3. Bits 0-31 of general register 3 remain unchanged.

Bits 96-111 of the ETE (the EKM) are ORed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask in control register 3.

In the 24-bit or 31-bit addressing mode, bits 224-255 of the ETE (bits 32-63 of the entry parameter) are loaded into bit positions 32-63 of general register 4, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, bits 192-255 of the ETE (the entry parameter), are loaded into bit positions 0-63 of general register 4.

## Stacking PROGRAM CALL

The following operations are performed when stacking PROGRAM CALL is specified.

The stacking process is performed to form a linkage-stack program-call state entry and place the following information in the state entry: current PSW (with an unpredictable PER mask), PSW-key mask, PASN, SASN, EAX, called-space identification, an indication of whether the resulting addressing mode is the 64-bit mode, numeric part of the program-call number, contents of general registers 0-15, and contents of access registers 0-15, and, if ASN-and-LX reuse is enabled, PASTEIN and SASTEIN. This is described in “Stacking Process” on page 5-80. The entry-type code in the state entry is 0001101 binary.

When bit 129 of the ETE (G) is zero, bit 31 of the PSW (the extended-addressing-mode bit) is set to zero, and bit 32 of the ETE (A) is placed in bit position 32 of the PSW (the basic-addressing-mode bit). (The addressing mode is set to the 24-bit mode if bit 32 is zero or to the 31-bit mode if bit 32 is one.) When bit 129 of the ETE is one, bits 31 and 32 of the PSW are set to one. (The 64-bit addressing mode is set.)

When the resulting addressing mode is the 24-bit or 31-bit mode, bits 33-62 of the ETE (the EIA), with 33 leftmost and one rightmost zeros appended, are placed in PSW bit positions 64-127 (the instruction address). When the resulting addressing mode is the 64-bit mode, bits 0-62 of the ETE (the EIA), with one rightmost zero appended, are placed in PSW bit positions 64-127.

Bit 63 of the ETE (P) is placed in PSW bit position 15 (the problem-state bit).

When bit 131 of the ETE (K) is zero, bits 8-11 of the PSW (the PSW key) remain unchanged. When bit 131 of the ETE is one, bits 136-139 of the ETE (the EK) replace the PSW key in the PSW.

When bit 132 of the ETE (M) is zero, bits 96-111 of the ETE (the EKM) are ORed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask in control register 3. When bit 132 of the ETE is one, bits 96-111 of the ETE replace the PSW-key mask in control register 3.

When bit 133 of the ETE (E) is zero, the EAX, bits 32-47 of control register 8, remains unchanged. When bit 133 of the ETE is one, bits 144-159 of the

ETE (the EEAX) replace the EAX in control register 8.

When bit 134 of the ETE (C) is zero, bits 16 and 17 of the PSW (the address-space-control bits) are set to 00 binary (primary-space mode). When bit 134 of the ETE is one, the address-space-control bits in the PSW are set to 01 binary (access-register mode).

When the resulting addressing mode is the 24-bit or 31-bit mode, bits 224-255 of the ETE (bits 32-63 of the entry parameter) are loaded into bit positions 32-63 of general register 4, and bits 0-31 of this register remain unchanged. When the resulting addressing mode is the 64-bit mode, bits 192-255 of the ETE (the entry parameter), are loaded into bit positions 0-63 of general register 4.

Key-controlled protection does not apply to references to the linkage stack, but low-address and DAT protection do apply.

### **PROGRAM CALL to Current Primary (PC-cp)**

If bits 80-95 of the ETE (the ASN), are zeros, PROGRAM CALL to current primary (PC-cp) is specified, and the execution of the instruction is completed after the operations described in “PROGRAM CALL PC-Number Translation” and either “Basic PROGRAM CALL” or “Stacking PROGRAM CALL” have been performed and the following operations have been performed.

The current PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of control register 3 to become the current SASN.

The current PASCE in control register 1 is placed in control register 7 to become the current SASCE.

If ASN-and-LX reuse is enabled, the current PASTEIN, bits 0-31 of control register 4, is placed in bit positions 0-31 of control register 3 to become the current SASTEIN.

The basic PC-cp operation is depicted in parts 1-3 of Figure 10-49 on page 10-84. The stacking PC-cp operation is depicted in parts 1, 4, and 5 of the figure.

### **PROGRAM CALL with Space Switching (PC-ss)**

If the ASN in the ETE is nonzero, PROGRAM CALL with space switching (PC-ss) is specified, and the execution of the instruction is completed after the

operations described in “PROGRAM CALL PC-Number Translation” and either “Basic PROGRAM CALL” or “Stacking PROGRAM CALL” have been performed and the following operations have been performed.

Bits 80-95 of the ETE (the ASN) are placed in bit positions 48-63 of control register 4 as the new PASN.

Bits 161-185 of the ETE, with six zeros appended on the right, are used as the real address of the ASTE designated by the new PASN. An ASX-translation exception is recognized if bit 0 of the ASTE is one.

Bits 64-127 of the ASTE (the ASCE) are placed in control register 1 as the new PASCE.

Bits 32-47 of the ASTE (the AX) are placed in bit positions 32-47 of control register 4 as the new authorization index.

If ASN-and-LX reuse is enabled, bits 352-383 of the ASTE (the ASTEIN) are placed in bit positions 0-31 of control register 4 as the new PASTEIN.

Bits 33-57 of the ASTE address are placed in bit positions 33-57 of control register 5 as the new primary-ASTE origin, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of the register remain unchanged.

In basic PROGRAM CALL, or in stacking PROGRAM CALL when bit 135 of the ETE (S) is zero, the PASN existing before the PASN is replaced from the ETE is placed in bit positions 48-63 of control register 3 to become the current SASN, and the PASCE existing before the PASCE is replaced from the ASTE is placed in control register 7 to become the current SASCE. If ASN-and-LX reuse is enabled, the PASTEIN existing before the PASTEIN is replaced from the ASTE is placed in bit positions 0-31 of control register 3 to become the current SASTEIN. (The SASN and SASCE are set equal to the old PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, the SASTEIN is set equal to the old PASTEIN.)

In stacking PROGRAM CALL when bit 135 of the ETE (S) is one, the SASN is replaced by the PASN after the PASN is replaced from the ETE, and the SASCE is replaced by the PASCE after the PASCE is replaced from the ASTE. If ASN-and-LX reuse is enabled, the SASTEIN is replaced by the PASTEIN after the PASTEIN is replaced from the ASTE. (The

SASN and SASCE are set equal to the new PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, the SASTEIN is set equal to the new PASTEIN.)

The description in this paragraph applies to use of the subspace-group facility. After the new PASCE has been placed in control register 1 and the new primary-ASTE origin has been placed in control register 5, if (1) the subspace-group-control bit, bit 54, in the PASCE is one, (2) the dispatchable unit is subspace active, and (3) the primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs before a replacement of the SASCE in control register 7 by the PASCE. Further details are in "Subspace-Replacement Operations" on page 5-66.

The PC-ss operation is depicted in parts 1 and 4-6 of Figure 10-49 on page 10-84.

### PROGRAM CALL Serialization

For both the PC-cp and PC-ss operations, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry or linkage-stack entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

### Special Conditions

The basic PROGRAM CALL operation can be performed successfully only when (1) the CPU is in the primary-space mode at the beginning of the operation, (2) the subsystem-linkage control, bit 0 of the linkage-table designation or linkage-first-table designation in the current primary ASN-second-table entry, is one, and (3) the extended-addressing-mode bit, bit 31 of the current PSW, equals the entry-extended-addressing-mode bit, bit 129 of the entry-table entry. Stacking PROGRAM CALL can be performed successfully only when the CPU is in the primary-space mode or access-register mode at the beginning of the operation and the subsystem-linkage control is one. In addition, PC-ss can be performed successfully only when the ASN-translation control, bit 44 of control register 14, is one. If any of these rules is violated, a special-operation exception is recognized.

When ASN-and-LX reuse is enabled and the LSTESN in the linkage-second-table entry is non-zero, that LSTESN must be equal to the LSTESN specified in bit positions 0-31 of general register 15; otherwise, an LSTE-sequence exception is recognized.

A stack-full or stack-specification exception may be recognized during the stacking process.

When, for PC-ss, the primary space-switch-event-control bit, bit 57 of control register 1, is one either before or after the execution of the instruction, a space-switch-event program interruption occurs after the operation is completed. A space-switch-event program interruption also occurs after the completion of a PC-ss operation if a PER event is reported.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-48 on page 10-82.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch or store, except for key-controlled protection, linkage-stack entry)
- Addressing (linkage-table or linkage-first-table designation in primary ASN-second-table entry; linkage-table entry; linkage-first-table entry; linkage-second-table entry, entry-table entry; ASN-second-table entry, PC-ss only)
- ASX translation (PC-ss only)
- EX translation
- LFX translation
- LSTE sequence
- LSX translation
- LX translation
- PC-translation specification
- Privileged operation (AND of AKM and PSW-key mask is zero in the problem state)
- Space-switch event (PC-ss only)
- Special operation
- Stack full (stacking PC only)
- Stack specification (stacking PC only)
- Subspace replacement (PC-ss only)
- Trace

**Programming Note:** The effective address from which a PC number is derived is subject to the

addressing mode in the current PSW. Therefore, bits 0-39 of the effective address in the 24-bit addressing mode, and bits 0-32 in the 31-bit addressing mode, are treated as containing zeros.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode or home-space mode.
8.A	Trace exceptions.
8.B.1	Addressing exception for access to linkage-table designation or linkage-first-table designation in primary ASN-second-table entry.
8.B.2	Special-operation exception due to subsystem-linkage control in linkage-table designation or linkage-first-table designation being zero.
<b>Note:</b> The LFX-translation, LSX-translation, and LSTE-sequence exceptions can be recognized only if ASN-and-LX reuse is enabled, and the LX-translation exception cannot be recognized in that case.	
8.B.3	LX-translation or LFX-translation exception due to linkage-table or linkage-first-table entry, respectively, being outside table.
8.B.4	Addressing exception for access to linkage-table or linkage-first-table entry.
8.B.5	LX-translation or LFX-translation exception due to 1 bit (bit 0) in linkage-table or linkage-first-table entry, respectively, being one.
8.B.6	Addressing exception for access to linkage-second-table entry.
8.B.7	LSX-translation exception due to 1 bit (bit 0) in linkage-second-table entry being one.
8.B.8	LSTE-sequence exception due to LSTE sequence number in linkage-second-table entry being nonzero and not equal to bits 0-31 of general register 15.
8.B.9	EX-translation exception due to entry-table entry being outside table.
8.B.10	Addressing exception for access to entry-table entry.
8.B.11	Special-operation exception due to the CPU being in access-register mode or extended-addressing-mode bit, bit 31 of PSW, not being equal to entry-extended-addressing-mode bit, bit 129 of entry-table entry (basic PC only).
8.B.12	PC-translation-specification exception due to invalid combination (bits 33-39 not zeros when resulting addressing mode is 24 bit) in entry-table entry.
8.B.13	Privileged-operation exception due to zero result from ANDing PSW-key mask and AKM in the problem state.
8.B.14	Special-operation exception due to ASN-translation control, bit 44 of control register 14, being zero (PC-ss only).
8.B.15	Addressing exception for access to ASN-second-table entry (PC-ss only).
8.B.16	ASX-translation exception due to 1 bit (bit 0) in ASN-second-table entry being one (PC-ss only).
<b>Note:</b> Subspace-replacement exceptions, which are not shown in detail in this figure, can occur with any priority after 8.B.16 and before 9.	

Figure 10-48. Priority of Execution: PROGRAM CALL (Part 1 of 2)

- 8.B.17 Access exceptions (fetch) for entry descriptor of the current linkage-stack entry (stacking PC only).
- Note:** Exceptions 8.B.18-8.B.23 can occur only if there is not enough remaining free space in the current linkage-stack section.
- 8.B.18 Stack-specification exception due to remaining-free-space value in current linkage-stack entry not being a multiple of 8.
- 8.B.19 Access exceptions (fetch) for second word of the trailer entry of the current section. The entry is presumed to be a trailer entry; its entry-type field is not examined (stacking PC only).
- 8.B.20 Stack-full exception due to forward-section validity bit in the trailer entry being zero (stacking PC only).
- 8.B.21 Access exceptions (fetch) for entry descriptor of the header entry of the next section (stacking PC only). This entry is presumed to be a header entry; its entry-type field is not examined.
- 8.B.22 Stack-specification exception due to not enough remaining free space in the next section (stacking PC only).
- 8.B.23 Access exceptions (store) for second word of the header entry of the next section. If there is no exception, the header is now called the current entry.
- 8.B.24 Access exceptions (store) for entry descriptor of the current entry and for the new state entry (stacking PC only).
9. Space-switch event (PC-ss only).

## PROGRAM RETURN

The PSW, except for the PER-mask bit, saved in the last linkage-stack state entry is restored as the current PSW. The PER mask in the current PSW remains unchanged. The contents of general registers 2-14 and access registers 2-14 also are restored from the state entry. When the entry-type code in the entry descriptor of the state entry is 0001101 binary, indicating a program-call state entry, (1) the primary ASN (PASN), secondary ASN (SASN), PSW-key

mask (PKM), and extended authorization index (EAX) in the control registers also are restored from the state entry and (2) if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the primary ASTE instance number (PASTEIN) and secondary ASTE instance number (SASTEIN) in the control registers also are restored from the state entry. When the entry-type code is 0001100 binary, indicating a branch state entry, the current PASN, SASN, PKM, EAX, PASTEIN, and SASTEIN remain unchanged.

The last state entry is located, and information in it is restored, as described in "Unstacking Process" on page 5-82. The state entry is logically deleted from

the linkage stack, and the linkage-stack-entry address in control register 15 is replaced by the address of the next preceding state or header entry. This also is described in “Unstacking Process”.

When the state entry is a program-call state entry, it causes a space-switching operation to occur if it contains a PASN that is not equal to the current PASN. When the state entry contains a PASN that is equal to the current PASN, the operation is called PROGRAM RETURN to current primary (PR-cp); when the state entry contains a PASN that is not equal to the current PASN, the operation is called PROGRAM RETURN with space switching (PR-ss). PASN translation occurs in PR-ss. SASN translation and authorization may occur in either PR-cp or PR-ss. The terms PR-cp and PR-ss do not apply when the state entry is a branch state entry.

When the ASN-and-LX-reuse facility is installed and enabled and PASN or SASN translation occurs, the PASTEIN or SASTEIN, respectively, saved in the state entry is compared to the ASTEIN in the located ASTE.

Key-controlled protection does not apply to accesses to the linkage stack, but low-address and DAT protection do apply.

The sections “PASN Translation,” “SASN Translation,” “SASN Authorization,” and “PROGRAM RETURN Serialization” apply only when the unstacked state entry is a program-call state entry. The functions described in those sections are not performed when the state entry is a branch state entry.

The actions involving the PASTEIN and SASTEIN occur only when ASN-and-LX reuse is enabled by the ASN-and-LX reuse control in control register 0.

### PASN Translation

If the new PASN is equal to the old PASN in bit positions 48-63 of control register 4, PASN translation is not performed, the PASTEIN in control register 4 remain as restored from the state entry, and the PASCE in control register 1 and primary-ASTE origin (PASTEO) in control register 5 are not changed. In this case, there is not a test of whether the new PASTEIN is equal to the old PASTEIN.

If the new PASN is not equal to the old PASN, the new PASN replaces the PASN in bit positions 48-63 of control register 4 and is translated to locate a

64-byte ASTE. The ASN table-lookup process is described in “ASN Translation” on page 3-26. The exceptions associated with ASN translation are collectively called ASN-translation exceptions. These exceptions and their priority are described in Chapter 6, “Interruptions.”

If ASN-and-LX reuse is enabled, the PASTEIN saved in bytes 180-183 of the state entry must equal the ASTEIN in bit positions 352-383 of the located ASTE; otherwise, an ASTE-instance exception is recognized.

Bits 64-127 of the ASTE are placed in control register 1 as the new PASCE.

Bits 32-47 of the ASTE are placed in bit positions 32-47 of control register 4 as the new AX. The PASN and PASTEIN in control register 4 remain as restored from the state entry.

Bits 33-57 of the ASTE address are placed in bit positions 33-57 of control register 5 as the new primary-ASTE origin, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of this register remain unchanged.

The description in this paragraph applies to use of the subspace-group facility when PASN translation has occurred. If (1) the subspace-group-control bit, bit 54, in the new PASCE is one, (2) the dispatchable unit is subspace active, and (3) the new primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the new PASCE in control register 1 are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs, in the case when the new SASN is equal to the new PASN, before the SASCE is set equal to the PASCE. Further details are in “Subspace-Replacement Operations” on page 5-66.

### SASN Translation

If the new SASN is equal to the new PASN, the SASCE in control register 7 is set equal to the new PASCE in control register 1. The SASTEIN, PKM, and SASN in control register 3 remain as restored from the state entry. In this case, there is not a test of whether the new SASTEIN is equal to the new PASTEIN.

If the new SASN is not equal to the new PASN, the new SASN is translated to locate a 64-byte ASTE.

If ASN-and-LX reuse is enabled, the SASTEIN saved in bytes 176-179 of the state entry must equal the ASTEIN in bit positions 352-383 of the located ASTE; otherwise, an ASTE-instance exception is recognized.

Bits 64-127 of the ASTE are placed in control register 7 as the new SASCE.

Control register 3 remains as restored from the state entry.

### SASN Authorization

If the new SASN is not equal to the new PASN, the authority-table origin (ATO) from the ASTE for the new SASN is used as the base for a third table lookup. The new authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in "ASN Authorization" on page 3-31.

The description in this paragraph applies to use of the subspace-group facility when SASN translation and authorization have occurred. If (1) the subspace-group-control bit, bit 54, in the new SASCE is one, (2) the dispatchable unit is subspace active, and (3) the ASTE origin obtained by SASN translation designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 are replaced by the same bits of the ASCE of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in "Subspace-Replacement Operations" on page 5-66.

### PROGRAM RETURN Serialization

When the unstacked state entry is a program-call state entry, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry or linkage-stack entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

### Special Conditions

The instruction can be executed successfully only when the CPU is in the primary-space mode or access-register mode at the beginning of the operation. In addition, the ASN-translation process can be

performed, for either the PASN or the SASN, only when the ASN-translation control, bit 44 of control register 14, is one. If either of these rules is violated, a special-operation exception is recognized.

A stack-empty, stack-operation, stack-specification, or stack-type exception may be recognized during the unstacking process.

If ASN-and-LX reuse is enabled, the restored PASTEIN must equal the ASTEIN in the located ASTE if PASN translation is performed, and the restored SASTEIN must equal the ASTEIN in the located ASTE if SASN translation is performed; otherwise, an ASTE-instance exception is recognized.

When, for PR-ss, the primary space-switch-event control, bit 57 of control register 1, is one either before or after the execution of the instruction, a space-switch-event program interruption occurs after the operation is completed. A space-switch-event program interruption also occurs after the completion of a PR-ss operation if a PER event is reported.

The PSW which is to be loaded by the instruction is not checked for validity before it is loaded. However, after loading, a specification exception is recognized, and a program interruption occurs, if any of bits 0, 2-4, 12, 24-30, and 33-63 of the PSW is a one, if bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros, if bits 31 and 32 are both zero and bits 64-103 are not all zeros, or if bits 31 and 32 are one and zero, respectively. In these cases, the operation is completed, and the resulting instruction-length code is 0. The specification exception, which in this case is listed as a program exception in this instruction, is described in "Early Exception Recognition" on page 6-8. It may be considered as occurring early in the process of preparing to execute the following instruction.

If a space-switch event is indicated and the PSW that was loaded by the instruction is invalid because of a reason described in the preceding paragraph, it is unpredictable whether the resulting instruction-length code is 0 or 1, or 0 or 2 if EXECUTE was used, or 0 or 3 if EXECUTE RELATIVE LONG was used.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-50 on page 10-91.

- 1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.
- 7. Special-operation exception due to DAT being off or the CPU being in secondary-space mode or home-space mode.
- 8.A Trace exceptions.
- 8.B.1 Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.
- 8.B.2 Stack-type exception due to current entry not being a state entry or header entry.
 

**Note:** Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.
- 8.B.3 Stack-operation exception due to unstack-suppression bit in the header entry being one.
- 8.B.4 Access exceptions (fetch) for second word of the header entry.
- 8.B.5 Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.
- 8.B.6 Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.
- 8.B.7 Stack-specification exception due to preceding entry being a header entry.
- 8.B.8 Stack-type exception due to preceding entry not being a state entry.
- 8.B.9 Stack-operation exception due to unstack-suppression bit being one in the state entry.
- 8.B.10 Access exceptions (fetch) for the state entry, and access exceptions (store) for entry descriptor of the entry preceding the state entry.
 

**Note:** Exceptions 8.B.11-8.B.15 and the event 9 can occur only if the state entry is a program-call state entry.
- 8.B.11 Special-operation exception due to the ASN-translation control, bit 44 of control register 14, being zero (if PASN or SASN translation occurs).
- 8.B.12 ASN-translation exceptions (if PASN translation occurs).
- 8.B.13 ASTE-instance exception due to new PASTEIN not being equal to ASTEIN in ASN-second-table entry located by PASN translation (if ASN-and-LX reuse enabled).
 

**Note:** Subspace-replacement exceptions for replacement of bits in the PASCE, which are not shown in detail in this figure, can occur with any priority after 8.B.13 and before 9.
- 8.B.14 ASN-translation exceptions (if SASN translation occurs).
- 8.B.15 ASTE-instance exception due to new SASTEIN not being equal to ASTEIN in ASN-second-table entry located by SASN translation (if ASN-and-LX reuse enabled).
 

**Note:** Subspace-replacement exceptions for replacement of bits in the SASCE, which are not shown in detail in this figure, can occur with any priority after 8.B.15 and before 9.
- 8.B.16 Secondary-authority exception due to authority-table entry being outside table (if SASN translation occurs).
- 8.B.17 Addressing exception for access to authority-table entry (if SASN translation occurs).
- 8.B.18 Secondary-authority exception due to S bit in authority-table entry being zero (if SASN translation occurs).
- 9. Space-switch event (PR-ss only).
- 10. Specification exception due to any PSW error of the type that causes an immediate interruption.

Figure 10-50. Priority of Execution: PROGRAM RETURN

**Resulting Condition Code:** The code is set as specified in the new PSW loaded.

## ***Program Exceptions:***

- Access (fetch and store, except key-controlled protection, linkage-stack entry)
  - Addressing (authority-table entry, if SASN translation occurs)
  - ASN translation (if PASN or SASN translation occurs)
  - ASTE instance (if ASN-and-LX reuse is enabled and PASN or SASN translation occurs)
  - Secondary authority (if SASN translation occurs)
  - Space-switch event
  - Special operation
  - Specification
  - Stack empty
  - Stack operation
  - Stack specification
  - Stack type
  - Subspace replacement (if PASN or SASN translation occurs)
  - Trace

**Programming Note:** Because PROGRAM CALL cannot be executed successfully in the secondary-space or home-space mode, PROGRAM RETURN is not intended to load a PSW specifying one of these translation modes. PROGRAM RETURN, unlike SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST, does not recognize a space-switch event because of loading a PSW that specifies the home-space mode.

# **PROGRAM TRANSFER**

PT	$R_1, R_2$	[RRE]
'B228'		$R_1$ $R_2$
0	16	24 28 31

## **PROGRAM TRANSFER WITH INSTANCE**

PTI	$R_1, R_2$	[RRE]
'B99E'		$R_1$ $R_2$
0	16	24 28 31

**Note:** In this instruction definition, the name “PROGRAM TRANSFER (WITH INSTANCE)” refers to the PROGRAM TRANSFER instruction and the PROGRAM TRANSFER WITH INSTANCE instruction.

Bits 32-63 of general register  $R_1$  are used as the new values for the PSW-key mask, the PASN, and the SASN. Bits 32-63 or 0-63 of general register  $R_2$ , depending on the current addressing mode, are used as the new values for the problem-state bit, basic-addressing-mode bit, and instruction address in the current PSW. In the PROGRAM TRANSFER WITH INSTANCE operation, bits 0-31 of general register  $R_1$  are an ASTEIN and are compared against the new value of the PASTEIN if the PASN is changed. In the PROGRAM TRANSFER operation, bits 0-31 of general register  $R_1$  are ignored.

The format of general registers  $R_1$  and  $R_2$  are shown in Figure 10-51.

Figure 10-51. Register Contents for PROGRAM TRANSFER (WITH INSTANCE)

When the contents of bit positions 48-63 of general register R<sub>1</sub> are equal to the current PASN, the operation is called PROGRAM TRANSFER (WITH INSTANCE) to current primary (PT-cp or PTI-cp); when the fields are not equal, the operation is called PROGRAM TRANSFER (WITH INSTANCE) with space switching (PT-ss or PTI-ss).

The contents of general register R<sub>2</sub> are used to update the problem-state bit and the instruction address in the current PSW and, in the 24-bit or 31-bit addressing mode, also the basic-addressing-mode bit in the current PSW. Bit 63 of general register R<sub>2</sub> is placed in the problem-state bit position, PSW bit position 15, unless the operation would cause PSW bit 15 to change from one to zero (problem state to supervisor state). If such a change would occur, a privileged-operation exception is recognized.

In the 24-bit or 31-bit addressing mode, bit 32 of general register R<sub>2</sub> replaces the basic-addressing-mode bit, bit 32 of the current PSW, and bits 33-62 of the register, with one rightmost zero appended, replace bits 33-63 of the instruction address in the PSW, bits 97-127 of the PSW. In the 64-bit addressing mode, bits 0-62 of general register R<sub>2</sub>, with one rightmost zero appended, replace the instruction address, and the basic-addressing-mode bit remains unchanged.

Bits 32-47 of general register R<sub>1</sub> are ANDed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask. Bits 0-31 of general register R<sub>1</sub> are ignored.

In any of the PT-cp, PTI-cp, PT-ss, and PTI-ss operations, the ASN specified by bits 48-63 of general register R<sub>1</sub> replaces the SASN in control register 3, and the SASCE in control register 7 is replaced by the final contents of control register 1.

In the PROGRAM TRANSFER operation, if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the SASTEIN in control register 3 is replaced by the final value of the PASTEIN in control register 4. This replacement occurs in the PROGRAM TRANSFER WITH INSTANCE operation regardless of the value of the ASN-and-LX-reuse control.

#### **PROGRAM TRANSFER (WITH INSTANCE) to Current Primary (PT-cp or PTI-cp)**

The PT-cp operation is depicted in part 1 of Figure 10-53 on page 10-97. The PTI-cp operation is depicted in part 1 of Figure 10-54 on page 10-99. The PT-cp or PTI-cp operation is completed when the common portion of the PROGRAM TRANSFER (WITH INSTANCE) operation, described above, is completed. The PASTEIN, authorization index, ASN, primary ASCE, and contents of control register 5 (primary-ASN-second-table-entry origin) are not changed by PT-cp or PTI-cp. In this case in the PTI-cp operation, there is not a test of whether the current PASTEIN equals the ASTEIN specified in bit positions 0-31 of general register R<sub>1</sub>; the ASTEIN is ignored.

#### **PROGRAM TRANSFER (WITH INSTANCE) with Space Switching (PT-ss or PTI-ss)**

If the ASN in bit positions 48-63 of general register R<sub>1</sub> is not equal to the current PASN, a PROGRAM TRANSFER (WITH INSTANCE) with space switching (PT-ss or PTI-ss) operation is specified, and the ASN is translated by means of a two-level table lookup.

The PT-ss operation is depicted in parts 1 and 2 of :figref Figure 10-53 on page 10-97. The PTI-ss operation is depicted in parts 1 and 2 of Figure 10-54 on page 10-99. The PT-ss or PTI-ss operation is completed as follows.

In PT-ss or PTI-ss, the contents of bit positions 48-63 of general register R<sub>1</sub> are used as an ASN, which is translated by means of a two-level table lookup.

Bits 48-57 of general register R<sub>1</sub> are a 10-bit AFX that is used to select an entry from the ASN first table. Bits 58-63 are a six-bit ASX that is used to select an entry from the ASN second table. The ASN table-lookup process is described in “ASN Translation” on page 3-26. The exceptions associated with ASN translation are collectively called “ASN-translation exceptions.” These exceptions and their priority are described in Chapter 6, “Interruptions.”

In PT-ss if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the reusable-ASN bit, bit 63, in the located ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In PTI-ss, regardless of the ASN-and-LX-reuse control, the controlled-ASN bit, bit 62, in the ASTE must be zero if the CPU is in the problem state at the beginning of the operation; otherwise, a special-operation exception is rec-

ognized. Also in PTI-ss, and regardless of the ASN-and-LX-reuse control and the reusable-ASN bit, the ASTEIN in bit positions 0-31 of general register R<sub>1</sub> must equal the ASTEIN in bit positions 352-383 of the ASTE; otherwise, an ASTE-instance exception is recognized.

The authority-table origin from the ASN-second-table entry (ASTE) is used as the base for a third table lookup. The current authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in "ASN Authorization" on page 3-31.

The PT-ss or PTI-ss operation is completed by placing bits 64-127 of the ASTE in control register 1 as the new PASCE and in control register 7 as the new SASCE. The contents of bit positions 32-47 of the ASTE replace the authorization index in bit positions 32-47 of control register 4. Bits 33-57 of the ASTE address are placed in bit positions 33-57 of control register 5 as the new primary-ASTE origin, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of this register remain unchanged. The ASN, bits 48-63 of general register R<sub>1</sub>, replaces the SASN and PASN in bit positions 48-63 of control registers 3 and 4. In PT-ss if ASN-and-LX reuse is enabled, and in PTI-ss regardless of that enablement, the ASTEIN in the ASTE replaces the SASTEIN and PASTEIN in bit positions 0-31 of control registers 3 and 4.

The description in this paragraph applies to use of the subspace-group facility. After the new PASCE has been placed in control register 1 and the new primary-ASTE origin has been placed in control register 5, if (1) the subspace-group-control bit, bit 54, in the PASCE is one, (2) the dispatchable unit is subspace active, and (3) the primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the PASCE in control register 1 are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs before a replacement of the SASCE in control register 7 by the PASCE. Further details are in "Subspace-Replacement Operations" on page 5-66.

### **PROGRAM TRANSFER (WITH INSTANCE) Serialization**

For any of the PT-cp, PTI-cp, PT-ss, and PTI-ss operations, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

### **Special Conditions**

The instruction can be executed only when the CPU is in the primary-space mode and the subsystem-linkage control, bit 0 of the linkage-table designation, or linkage-first-table designation in the current primary ASN-second-table entry, is one. If the CPU is in the real mode, secondary-space mode, access-register mode, or home-space mode, or if the subsystem-linkage control is zero, a special-operation exception is recognized.

In PT-ss when ASN-and-LX reuse is enabled, the reusable-ASN bit in the ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In PTI-ss, regardless of the ASN-and-LX-reuse control, a special-operation exception is recognized if the controlled-ASN bit in the ASTE is one and the CPU is in the problem state at the beginning of the operation, and an ASTE-instance exception is recognized if the ASTEIN in general register R<sub>1</sub> is not equal to the ASTEIN in the ASTE.

Bit 63 of general register R<sub>2</sub> is placed in the problem-state bit position, PSW bit position 15, unless the operation would cause PSW bit 15 to change from one to zero (problem state to supervisor state). If such a change would occur, a privileged-operation exception is recognized.

In the 24-bit or 31-bit addressing mode, the instruction is completed only if bits 32-39 of general register R<sub>2</sub> specify a valid combination of PSW bits 32 and 97-103. If bit 32 of general register R<sub>2</sub> is zero and bits 33-39 are not all zeros, a specification exception is recognized.

In addition to the above requirements, when a PT-ss or PTI-ss instruction is specified, the ASN-translation control, bit 44 of control register 14, must be one; otherwise, a special-operation exception is recognized.

When, for PT-ss or PTI-ss, the primary space-switch-event-control bit, bit 57 of register 1, is one either before or after the execution of the instruction, a

space-switch-event program interruption occurs after the operation is completed. A space-switch-event program interruption also occurs after the completion of a PT-ss or PTI-ss operation if a PER event is reported.

The operation is suppressed on all addressing exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-52 on page 10-96.

**Condition Code:** The code remains unchanged.

#### **Program Exceptions:**

- Addressing (linkage-table or linkage-first-table designation in primary ASN-second-table entry; authority-table entry, PT-ss and PTI-ss only)
- ASN translation (PT-ss and PTI-ss only)
- ASTE instance (PTI-ss only)
- Operation (if ASN-and-LX-reuse facility is not installed, PTI only)
- Primary authority (PT-ss and PTI-ss only)
- Privileged operation (attempt to set the supervisor state when in the problem state)
- Space-switch event (PT-ss and PTI-ss only)
- Special operation
- Specification
- Subspace replacement (PT-ss and PTI-ss only)
- Trace

#### **Programming Notes:**

1. The operation of PROGRAM TRANSFER (PT) is such that it may be used to restore the CPU to the state saved by a previous basic PROGRAM CALL operation. This restoration is accomplished by issuing PT 3,14. Though general registers 3 and 14 are not restored to their original values, the PASN, PSW-key mask, problem-state bit, and instruction address are restored, and the

authorization index, PASCE, and primary-ASN-second-table-entry origin are made consistent with the restored PASN. In the 24-bit or 31-bit addressing mode, the basic-addressing-mode bit also is restored. If ASN-and-LX reuse is enabled, the PASTEIN also is made consistent with the restored PASN. Note that the SASN is not saved by PROGRAM CALL or restored by PROGRAM TRANSFER; PROGRAM TRANSFER sets the SASN equal to the restored PASN. PROGRAM TRANSFER WITH INSTANCE is the same as PROGRAM TRANSFER except that the PASTEIN is made consistent regardless of ASN-and-LX-reuse enablement.

2. With proper authority, and while being executed in a common area, PROGRAM TRANSFER (WITH INSTANCE) may be used to change the primary address space to any desired space. The secondary address space is also changed to be the same as the new primary address space.
3. Unlike the RR-format branch instructions, a value of zero in the R<sub>2</sub> field for PROGRAM TRANSFER (WITH INSTANCE) designates general register 0, and branching occurs.
4. A program given control by a basic PROGRAM CALL operation can use EXTRACT SECONDARY ASN AND INSTANCE to obtain the ASTEIN to be used by PROGRAM TRANSFER WITH INSTANCE to return to the calling program or by SET SECONDARY ASN WITH INSTANCE to restore its secondary address space after a change of that space. This EXTRACT SECONDARY ASN AND INSTANCE instruction should be executed while the original secondary space remains continuously the secondary space; otherwise, depending on actions by the control program, EXTRACT SECONDARY ASN AND INSTANCE may return an ASTEIN that allows return to or use of a conceptually incorrect secondary space for which the ASTEIN has been changed.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B.1	Operation exception (PTI only, if the ASN-and-LX-reuse facility is not installed).
7.B.2	Special-operation exception due to DAT being off or the CPU being in secondary-space mode, access-register mode, or home-space mode.
8.A	Trace exceptions.
8.B.1	Addressing exception for access to linkage-table designation or linkage-first-table designation in primary ASN-second-table entry.
8.B.2	Special-operation exception due to subsystem-linkage control in linkage-table designation or linkage-first-table designation being zero.
8.B.3	Privileged-operation exception due to attempt to set the supervisor state when in the problem state.
8.B.4	Specification exception due to invalid combination (bit 32 is zero and bits 33-39 not zeros) in general register R <sub>2</sub> in 24-bit or 31-bit addressing mode.
8.B.5	Special-operation exception due to the ASN-translation control, bit 44 of control register 14, being zero (PT-ss or PTI-ss only).
8.B.6	ASN-translation exceptions (PT-ss and PTI-ss only).
8.B.7	Special-operation exception due to ASN-and-LX reuse enabled and reusable-ASN bit in ASN-second-table entry being one (PT-ss only).
8.B.8	Special-operation exception due to controlled-ASN bit in ASN-second-table entry being one and CPU being in problem state at the beginning of the operation (PTI-ss only).
8.B.9	ASTE-instance exception due to ASTEIN in general register R <sub>1</sub> not being equal to ASTEIN in ASN-second-table entry (PTI-ss only).
<b>Note:</b> Subspace-replacement exceptions, which are not shown in detail in this figure, can occur with any priority after 8.B.9 and before 9.	
8.B.10	Primary-authority exception due to authority-table entry being outside table (PT-ss and PTI-ss only).
8.B.11	Addressing exception for access to authority-table entry (PT-ss and PTI-ss only).
8.B.12	Primary-authority exception due to P bit in authority-table entry being zero (PT-ss and PTI-ss only).
9.	Space-switch event (PT-ss and PTI-ss only).

Figure 10-54. Execution of PROGRAM TRANSFER WITH INSTANCE (Part 2 of 2).

## PURGE ALB

PALB	[RRE]
'B248'	

0                  16                  31

The ART-lookaside buffer (ALB) of this CPU is cleared of entries. No change is made to the contents of addressable storage or registers.

The ALB appears cleared of its original contents beginning with the execution of the next sequential instruction. The operation is not signaled to any other CPU.

A serialization function is performed.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Privileged operation

## PURGE TLB

PTLB	[S]
'B20D'	

0                  16                  31

The translation-lookaside buffer (TLB) of this CPU is cleared of entries. No change is made to the contents of addressable storage or registers.

The TLB appears cleared of its original contents beginning with the fetching of the next sequential instruction. The operation is not signaled to any other CPU.

A serialization function is performed.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Privileged operation

## RESET REFERENCE BIT EXTENDED

RRBE	R <sub>1</sub> , R <sub>2</sub>	[RRE]
'B22A'	R <sub>1</sub> R <sub>2</sub>	24 28 31

0                  16                  24                  28                  31

The reference bit in the storage key for the 4K-byte block that is addressed by the contents of general register R<sub>2</sub> is set to zero. The contents of general register R<sub>1</sub> are ignored.

In the 24-bit addressing mode, bits 40-51 of general register R<sub>2</sub> designate a 4K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R<sub>2</sub> designate a 4K-byte block in real storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R<sub>2</sub> designate a 4K-byte block in real storage, and bits 52-63 of the register are ignored.

Because it is a real address, the address designating the storage block is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The remaining bits of the storage key, including the change bit, are not affected.

The condition code is set to reflect the state of the reference and change bits before the reference bit is set to zero.

**Resulting Condition Code:**

- 0 Reference bit zero; change bit zero
- 1 Reference bit zero; change bit one
- 2 Reference bit one; change bit zero
- 3 Reference bit one; change bit one

**Program Exceptions:**

- Addressing (address specified by general register R<sub>2</sub>)
- Privileged operation

# **RESUME PROGRAM**

RP	$D_2(B_2)$	[S]
'B277'	$B_2$	$D_2$
0	16	20

Certain contents of the current PSW and of access register and general register B<sub>2</sub> are replaced from three or four corresponding fields in the second operand. The size of the PSW field in the second operand, the size or number of general-register fields in the second operand, and the offsets of the fields in the second operand are specified in a parameter list that immediately follows the instruction in the instruction address space.

The instruction address space is the address space from which instructions are fetched. It is composed of real addresses if DAT is off.

The first 64 bits of the parameter list have the following format:

0 0 0 0 0 0 0 0 0 0 0 0   P R D	Offset of PSW Field
0	13 14 15 16
Offset of AR Field	Offset of GR Field 1
32	48

When bits 14 (R) and 15 (D) of the parameter list are both one, the list is an additional 16 bits in length, as follows:

## Offset of GR Field 2

Bit 13 of the parameter list (P) specifies the size of the PSW field in the second operand. The field is eight bytes if bit 13 is zero or 16 bytes if bit 13 is one.

Bits 14 and 15 of the parameter list (R and D) provide specifications about one or two general-register fields in the second operand, as follows:

- When bit 14 is zero, then bit 15 is ignored, the general-register field 1 in the second operand is four bytes, from which bits 32-63 of general register  $B_2$  will be replaced, there is not a general-register field 2 in the second operand, and bits 0-31 of general register  $B_2$  will remain unchanged.

- When bit 14 is one and bit 15 is zero, then the general-register field 1 is eight bytes, from which bits 0-63 of general register B<sub>2</sub> will be replaced, and there is not a general-register field 2.
  - When bits 14 and 15 are both one, then the general-register fields 1 and 2 are both four bytes, bits 32-63 of general register B<sub>2</sub> will be replaced from field 1, and bits 0-31 of the register will be replaced from field 2. (The letter “D” stands for disjoint.)

Bits 16-31 of the parameter list are an unsigned binary integer that is the offset in bytes from the beginning of the second operand to a field that has the format of an eight-byte or 16-byte PSW, depending on bit 13, and from which fields in the current PSW will be replaced. Bits 32-47 similarly are an offset to a four-byte field from which the contents of access register B<sub>2</sub> will be replaced. Bits 48-63 similarly are an offset to a four-byte or eight-byte field, depending on bits 14 and 15, from which bits 32-63 or 0-63, respectively, of general register B<sub>2</sub> will be replaced. If bits 64-79 of the parameter list exist, they similarly are an offset to a four-byte field from which bits 0-31 of general register B<sub>2</sub> will be replaced.

Bits 0-12 of the parameter list must be zeros; otherwise, a specification exception is recognized.

An eight-byte second-operand PSW field has the ESA/390 PSW format, as follows:

A 16-byte second-operand PSW field has the z/Architecture PSW format, as follows:

Fields in the current PSW are replaced from the corresponding fields in the PSW field in the second operand. The PSW fields that are replaced are as follows:

PSW Bits	Field Name
16 and 17	Address-space control (AS)
18 and 19	Condition code (CC)
20-23	Program mask
31	Extended addressing mode (EA)
32	Basic addressing mode (BA)
64-127	Instruction address

The remaining fields in the PSW field in the second operand are ignored. Specifically, there is no test for whether bit 12 is one in an eight-byte PSW or zero in a 16-byte PSW. There is also no test for whether bit 31 is zero in an eight-byte PSW.

Unassigned fields in the PSW may be assigned in the future and may then be among those restored by RESUME PROGRAM. Therefore, these fields in the PSW field in the second operand should contain zeros; otherwise, the program may not operate compatibly in the future.

When PSW bits 64-127 are replaced from an eight-byte PSW field in the second operand, they are replaced with bits 33-63 of the field, with 33 zeros appended on the left.

The fields in the second operand are fetched before the contents of access register  $B_2$  and general register  $B_2$  are changed.

When RESUME PROGRAM is the target of an execute-type instruction, the parameter list immediately follows the RESUME PROGRAM instruction, not the execute-type instruction.

The references to the parameter list are storage-operand fetches, not instruction fetches.

### Special Conditions

The instruction is completed only if the bits 31, 32, and 64-127 that are to be placed in the current PSW are valid for placement in the PSW. If bits 31 and 32 are both zero and bits 64-103 are not all zeros, if bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros, if bits 31 and 32 are one and zero, respectively, or if bit 127 is one, a specification exception is recognized.

The CPU must be in the supervisor state when the operation is to set the home-space mode; otherwise, a privileged-operation exception is recognized. When DAT is off, the values of bits 16 and 17 of the PSW field in the second operand are not tested.

When the CPU is in the home-space mode either before or after the operation, but not both before and after the operation, a space-switch-event program interruption occurs after the operation is completed if any of the following is true: (1) the primary space-switch-event control, bit 57 of the primary address-space-control element (ASCE) in control register 1, is one; (2) the home space-switch-event control, bit 57 of the home ASCE in control register 13, is one; or (3) a PER event is to be indicated.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-55 on page 10-104.

**Resulting Condition Code:** The code is set as specified by the new condition code loaded.

### Program Exceptions:

- Access (fetch, parameter list and operand 2)
- Privileged operation (attempt to set the home-space mode when in the problem state)
- Space-switch event
- Specification
- Trace

### Programming Notes:

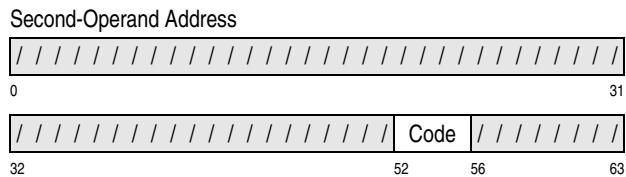

1. As described in “Instruction Fetching” on page 5-89, the bytes of an instruction may be fetched piecemeal, and the instruction may be fetched multiple times for a single execution. Therefore, the results are unpredictable when instructions are fetched for execution from storage that is being changed by another CPU or a channel program. This warning is particularly applicable when RESUME PROGRAM is the target of an execute-type instruction since the execute-type instruction may be refetched in order to generate, from its second operand, the address of the parameter list used by RESUME PROGRAM. If the execute-type instruction is refetched, there is not necessarily a test for whether storage still contains either the execute-

- 1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.
- 7. Access exceptions for second instruction halfword.
- 8.A Trace exceptions.
- 8.B.1 Access exceptions for bits 0-63 of parameter list.
- 8.B.2 Specification exception due to bits 0-12 of parameter list not being all zeros.
- 8.B.3 Access exceptions for bits 64-79 of parameter list, if these bits exist.
- 8.B.4 Access exceptions for second operand.
- 8.B.5 Privileged-operation exception due to attempt to set the home-space mode when in the problem state.
- 8.B.6 Specification exception due to invalid values in bit positions 31, 32, and 64-127 of PSW in second operand.
- 9. Space-switch event.

*Figure 10-55. Priority of Execution: RESUME PROGRAM*

- 1. type instruction or the RESUME PROGRAM instruction.
- 2. The storage-operand references for RESUME PROGRAM may be multiple-access references. (See "Storage-Operand Consistency" on page 5-95.)

The following figure summarizes the operation of SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST:

## SET ADDRESS SPACE CONTROL

SAC	D <sub>2(B<sub>2</sub>)</sub>	[S]
0	'B219'	B <sub>2</sub> D <sub>2</sub>

## SET ADDRESS SPACE CONTROL FAST

SACF	D <sub>2(B<sub>2</sub>)</sub>	[S]
0	'B279'	B <sub>2</sub> D <sub>2</sub>

Bits 52-55 of the second-operand address are used as a code to set the address-space-control bits in the PSW. The second-operand address is not used to address data; instead, bits 52-55 form the code. Bits 0-51 and 56-63 of the second-operand address are ignored. Bits 52 and 53 of the second-operand address must be zeros; otherwise, a specification exception is recognized.

Result in PSW Bits 16 and 17		
Code	Name of Mode	
0000	Primary space	00
0001	Secondary space	10
0010	Access register	01
0011	Home space	11
All others	Invalid	

The CPU must be in the supervisor state when the operation is to set the home-space mode; otherwise, a privileged-operation exception is recognized.

For SET ADDRESS SPACE CONTROL, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. This function is not performed for SET ADDRESS SPACE CONTROL FAST.

### Special Conditions

For SET ADDRESS SPACE CONTROL, the operation is performed only when the secondary-space control, bit 37 of control register 0, is one and DAT is on. When either the secondary-space control is zero or DAT is off, a special-operation exception is recog-

nized. The same rules apply also to SET ADDRESS SPACE CONTROL FAST, except that whether the secondary-space control is tested is unpredictable.

When the CPU is in the home-space mode either before or after the operation, but not both before and after the operation, a space-switch-event program interruption occurs after the operation is completed if any of the following is true: (1) the primary space-switch-event control, bit 57 of the primary address-space-control element (ASCE) in control register 1, is one; (2) the home space-switch-event control, bit 57 of the home ASCE in control register 13, is one; or (3) a PER event is to be indicated.

The priority of recognition of program exceptions for the instructions is shown in Figure 10-56 on page 10-105.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Privileged operation (attempt to set the home-space mode in the problem state)
- Space-switch event
- Special operation
- Specification

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off.
7.C	Special-operation exception due to the secondary-space control, bit 37 of control register 0, being zero. May be omitted for SET ADDRESS SPACE CONTROL FAST.
8.	Privileged-operation exception due to attempt to set home-space mode when in problem state.
9.	Specification exception due to non-zero value in bit positions 52 and 53 of second-operand address.
10.	Space-switch event.

Figure 10-56. Priority of Execution: SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST

#### Programming Notes:

1. SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST are defined in such a way that the mode to be set can be placed directly in the displacement field of the instruction or can be specified from the same bit positions of a general register as those in which the mode is saved by INSERT ADDRESS SPACE CONTROL.
2. SET ADDRESS SPACE CONTROL FAST may provide better performance than SET ADDRESS SPACE CONTROL, depending on the model.
3. Because SET ADDRESS SPACE CONTROL FAST does not perform the serialization function, it does not cause copies of prefetched instructions to be discarded. To ensure predictable results after SET ADDRESS SPACE CONTROL FAST is used to switch to or from the home-space mode, the program must cause prefetched instructions to be discarded before an instruction is executed in a location that does not contain the same instruction in both the primary and home address spaces. The operations that cause prefetched instructions to be discarded are described in “Instruction Fetching” on page 5-89.
4. If a program stores into the instruction stream at a location following a subsequent SET ADDRESS SPACE CONTROL FAST instruction, and the SET ADDRESS SPACE CONTROL FAST instruction changes the translation mode either from or to either the access-register mode or the home-space mode, a copy of a prefetched instruction may be executed instead of the value that was stored. To avoid this situation, either SET ADDRESS SPACE CONTROL must be used instead of SET ADDRESS SPACE CONTROL FAST or some other means must be used to cause prefetched instructions to be discarded after the conceptual store occurs.

## SET CLOCK

SCK	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B204'	B <sub>2</sub> D <sub>2</sub>

The current value of the TOD clock is replaced by the contents of the doubleword designated by the sec-

ond-operand address, and the clock enters the stopped state.

The doubleword operand replaces the contents of the clock, as determined by the resolution of the clock. Only those bits of the operand are set in the clock that correspond to the bit positions which are updated by the clock; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the clock. In some models, starting at or to the right of bit position 52, the rightmost bits of the second operand are ignored, and the corresponding positions of the clock which are implemented are set to zeros. Zeros are also placed in positions to the right of bit position 63 of the clock.

After the clock value is set, the clock enters the stopped state. The clock leaves the stopped state to enter the set state and resume incrementing under control of the TOD-clock-sync control, bit 34 of control register 0, of the CPU which most recently caused the clock to enter the stopped state. When the bit is zero, the clock enters the set state at the completion of the instruction. When the bit is one, the clock remains in the stopped state until the bit is set to zero or until another CPU executes a SET CLOCK instruction affecting the clock. If an external time reference (ETR) is installed, a signal from the ETR may be used to set the set state from the stopped state. When the system is not in the interpretive-execution mode, and an external time reference (ETR) is not attached to the configuration, the TOD-clock-sync control is treated as being zero, regardless of its actual value; in this case, the clock enters the set state and resumes incrementing upon completion of the instruction.

The value of the clock is changed and the clock is placed in the stopped state only if the manual TOD-clock control of any CPU in the configuration is set to the enable-set position or the TOD-clock-control-override control, bit 42 of control register 14, is one. If the TOD-clock control of all CPUs is set to the secure position and the TOD-clock-control-override control is zero, the value and state of the clock are not changed. Whether the clock is set or remains unchanged is distinguished by condition codes 0 and 1, respectively.

When the clock is not operational, the value and state of the clock are not changed, regardless of the

settings of the TOD-clock control and the TOD-clock-control-override control, and condition code 3 is set.

## **Special Conditions**

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

### ***Resulting Condition Code:***

- 0 Clock value set
- 1 Clock value secure
- 2 --
- 3 Clock in not-operational state

### ***Program Exceptions:***

- Access (fetch, operand 2)
- Privileged operation
- Specification

### ***Programming Notes:***

1. SET CLOCK should be issued only while all other activity on all CPUs in the configuration has been suspended. This activity should not be resumed until after the TOD clock has entered the set state.
2. To ensure predictable operation of the CPU timer after the TOD clock enters the set state, SET CPU TIMER should be issued on all CPUs in the configuration.
3. To ensure predictable operation of clock-comparator interruptions after the TOD clock enters the set state, one of the following instructions should be issued on each CPU in the configuration: SET CLOCK COMPARATOR (SCKC), STORE CLOCK (STCK), or STORE CLOCK EXTENDED (STCKE). (Execution of STCKF does not necessarily include the interlocks required for this special situation.)
4. SET CLOCK is provided for compatibility purposes. It is recommended that, where possible, the program use the PTFF control function PTFF-STO (Set TOD Offset), rather than SET CLOCK.

## SET CLOCK COMPARATOR

SCKC	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B206'	B <sub>2</sub> D <sub>2</sub>

16 20 31

The current value of the clock comparator is replaced by the contents of the doubleword designated by the second-operand address.

Only those bits of the operand are set in the clock comparator that correspond to the bit positions to be compared with the TOD clock; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the clock comparator.

### Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification

## SET CLOCK PROGRAMMABLE FIELD

SCKPF	[E]
0	'0107'

15

Bits 48-63 of general register 0 are placed in bit positions 16-31 of the TOD programmable register. Zeros are placed in bit positions 0-15 of the TOD programmable register.

### Special Conditions

Bits 32-47 of general register 0 must be zeros; otherwise, a specification exception is recognized. Bits 0-31 of general register 0 are ignored.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Privileged operation
- Specification

**Programming Note:** The values in the TOD programmable registers of a configuration should be the same and should be unique within a multiple-configuration system.

## SET CPU TIMER

SPT	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B208'	B <sub>2</sub> D <sub>2</sub>

16 20 31

The current value of the CPU timer is replaced by the contents of the doubleword designated by the second-operand address.

Only those bits of the operand are set in the CPU timer that correspond to the bit positions to be updated; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the CPU timer.

### Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification

## SET PREFIX

SPX	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B210'	B <sub>2</sub> D <sub>2</sub>

16 20 31

The contents of bit positions 33-50 of the prefix register are replaced by the contents of bit positions 1-18 of the word at the location designated by the second-operand address. The ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB) of this CPU are cleared of entries.

After the second operand is fetched, the value is tested for validity before it is used to replace the contents of the prefix register. Bits 1-18 of the operand with 13 zeros appended on the right and 33 zeros appended on the left are used as an absolute address of the 8K-byte new prefix area in storage. This address is treated as a 64-bit address regardless of the addressing mode specified by the current PSW. The two 4K-byte blocks within the new prefix area are accessed; if either is not available in the configuration, an addressing exception is recognized, and the operation is suppressed. The accesses to the blocks are not subject to protection; however, the accesses may cause the reference bits for the blocks to be set to ones.

If the operation is completed, the new prefix is used for any interruptions following the execution of the instruction and for the execution of subsequent instructions. The contents of bit positions 0 and 19-31 of the second operand are ignored.

The ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB) are cleared of entries. The ALB and TLB appear cleared of their original contents, beginning with the fetching of the next sequential instruction.

A serialization function is performed before or after the second operand is fetched and again after the operation is completed.

### Special Conditions

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch, operand 2)
- Addressing (new prefix area)

- Privileged operation
- Specification

## SET PSW KEY FROM ADDRESS

SPKA	D <sub>2</sub> (B <sub>2</sub> )	[S]
'B20A'	B <sub>2</sub>	D <sub>2</sub>

The four-bit PSW key, bits 8-11 of the current PSW, is replaced by bits 56-59 of the second-operand address.

The second-operand address is not used to address data; instead, bits 56-59 of the address form the new PSW key. Bits 0-55 and 60-63 of the second-operand address are ignored.

### Special Conditions

In the problem state, the execution of the instruction is subject to control by the PSW-key mask in control register 3. When the bit in the PSW-key mask corresponding to the PSW-key value to be set is one, the instruction is executed successfully. When the selected bit in the PSW-key mask is zero, a privileged-operation exception is recognized. In the supervisor state, any value for the PSW key is valid.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Privileged operation (selected PSW-key-mask bit is zero in the problem state)

### Programming Notes:

1. The format of SET PSW KEY FROM ADDRESS permits the program to set the PSW key either from the general register designated by the B<sub>2</sub> field or from the D<sub>2</sub> field in the instruction itself.
2. When one program requests another program to access a location designated by the requesting program, SET PSW KEY FROM ADDRESS can be used by the called program to verify that the requesting program is authorized to make this access, provided the storage location of the called program is not protected against fetching. The called program can perform the verification by replacing the PSW key with the requesting-

program PSW key before making the access and subsequently restoring the called-program PSW key to its original value. Caution must be exercised, however, in handling any resulting protection exceptions since such exceptions may cause the operation to be terminated. See TEST PROTECTION and the associated programming notes for an alternative approach to the testing of addresses passed by a calling program.

## SET SECONDARY ASN

SSAR	R <sub>1</sub>	[RRE]
'B225'	R <sub>1</sub>	

0                  16          24          28          31

## SET SECONDARY ASN WITH INSTANCE

SSAIR	R <sub>1</sub>	[RRE]
'B99F'	R <sub>1</sub>	

0                  16          24          28          31

**Note:** In this instruction definition, the name “SET SECONDARY ASN (WITH INSTANCE)” refers to the SET SECONDARY ASN instruction and the SET SECONDARY ASN WITH INSTANCE instruction.

The ASN specified in bit positions 48-63 of general register R<sub>1</sub> replaces the secondary ASN in control register 3, and the address-space-control element corresponding to that ASN replaces the SASCE in control register 7.

The contents of bit positions 48-63 of general register R<sub>1</sub> are called the new ASN. For SET SECONDARY ASN WITH INSTANCE, bits 0-31 of the register are an STEIN and are compared against the new SASTEIN if the SASTEIN is not set equal to the PASTEIN, and bits 32-47 of the register are ignored. For SET SECONDARY ASN, bits 0-47 of the register are ignored.

When the new ASN is equal to the current PASN, the operation is called SET SECONDARY ASN (WITH INSTANCE) to current primary (SSAR-cp or SSAIR-cp); when the fields are not equal, the operation is called SET SECONDARY ASN (WITH INSTANCE) with space switching (SSAR-ss or SSAIR-ss). The SSAR-cp and SSAR-ss operations are depicted in

Figure 10-58 on page 10-112. The SSAIR-cp and SSAIR-ss operations are depicted in Figure 10-59 on page 10-113.

### SET SECONDARY ASN (WITH INSTANCE) to Current Primary (SSAR-cp or SSAIR-cp)

In the SSAR-cp or SSAIR-cp operation, the new ASN is equal to the PASN. The new ASN replaces the SASN, bits 48-63 of control register 3; the PASCE in control register 1 replaces the SASCE in control register 7.

In SSAR-cp, if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the SASTEIN in bit positions 0-31 of control register 3 is replaced by the PASTEIN in bit positions 0-31 of control register 4. This replacement occurs in SSAIR-cp regardless of the value of the ASN-and-LX-reuse control. In SSAIR-cp, there is not a test of whether the current PASTEIN equals the ASTEIN in bit positions 0-31 of general register R<sub>1</sub>; the ASTEIN is ignored. The operation is completed.

### SET SECONDARY ASN (WITH INSTANCE) with Space Switching (SSAR-ss or SSAIR-ss)

In the SSAR-ss or SSAIR-ss operation, the new ASN is not equal to the PASN, and the new ASN is translated by means of a two-level table lookup. Bits 0-9 of the new ASN (bits 48-57 of the register) are a 10-bit AFX which is used to select an entry from the ASN first table. Bits 10-15 of the new ASN (bits 58-63 of the register) are a six-bit ASX which is used to select an entry from the ASN second table. The two-level lookup is described in “ASN Translation” on page 3-26. The exceptions associated with ASN translation are collectively called “ASN-translation exceptions.” These exceptions and their priority are described in Chapter 6, “Interruptions.”

In SSAR-ss, if the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0, the reusable-ASN bit, bit 63, in the located ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In SSAIR-ss, regardless of the ASN-and-LX-reuse control, the controlled-ASN bit, bit 62, in the ASTE must be zero in the problem state; otherwise, a special-operation exception is recognized. Also in SSAIR-ss, and regardless of the ASN-and-LX-reuse control and the reusable-ASN bit, the ASTEIN in bit positions 0-31 of general register R<sub>1</sub>

must equal the ASTEIN in bit positions 352-383 of the ASTE; otherwise, an ASTE-instance exception is recognized.

The ASN-second-table entry (ASTE) obtained as a result of the second lookup contains the address-space-control element and the authority-table origin and length associated with the ASN.

The authority-table origin from the ASTE is used as a base for a third table lookup. The current authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in "ASN Authorization" on page 3-31.

The new ASN, bits 48-63 of general register R<sub>1</sub>, replaces the SASN, bits 48-63 of control register 3. The address-space-control element in the ASTE replaces the SASCE in control register 7. In SSAR-ss if ASN-and-LX reuse is enabled, and in SSAIR-ss regardless of that enablement, the ASTEIN in the ASTE replaces the SASTEIN in bit positions 0-31 of control register 3.

The description in this paragraph applies to use of the subspace-group facility. After the new SASCE has been placed in control register 7, if (1) the subspace-group-control bit, bit 54, in the SASCE is one, (2) the dispatchable unit is subspace active, and (3) the ASTE obtained by ASN translation is the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the SASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in "Subspace-Replacement Operations" on page 5-66.

### **SET SECONDARY ASN (WITH INSTANCE) Serialization**

For any of the SSAR-cp, SSAIR-cp, SSAR-ss, and SSAIR-ss operations, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

### **Special Conditions**

The operation is performed only when the ASN-translation control, bit 44 of control register 14, is one and DAT is on. When either the ASN-translation-control bit is zero or DAT is off, a special-operation exception is recognized.

In SSAR-ss when ASN-and-LX reuse is enabled, the reusable-ASN bit in the ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In SSAIR-ss, regardless of the ASN-and-LX-reuse control, a special-operation exception is recognized if the controlled-ASN bit in the ASTE is one and the CPU is in the problem state, and an ASTE-instance exception is recognized if the ASTEIN in general register R<sub>1</sub> is not equal to the ASTEIN in the ASTE.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-57 on page 10-111.

**Condition Code:** The code remains unchanged.

### **Program Exceptions:**

- Addressing (authority-table entry, SSAR-ss and SSAIR-ss only)
- ASN translation (SSAR-ss and SSAIR-ss only)
- ASTE instance (SSAIR-ss only)
- Operation (if ASN-and-LX-reuse facility is not installed, SSAIR only)
- Secondary authority (SSAR-ss and SSAIR-ss only)
- Special operation
- Subspace replacement (SSAR-ss and SSAIR-ss only)
- Trace

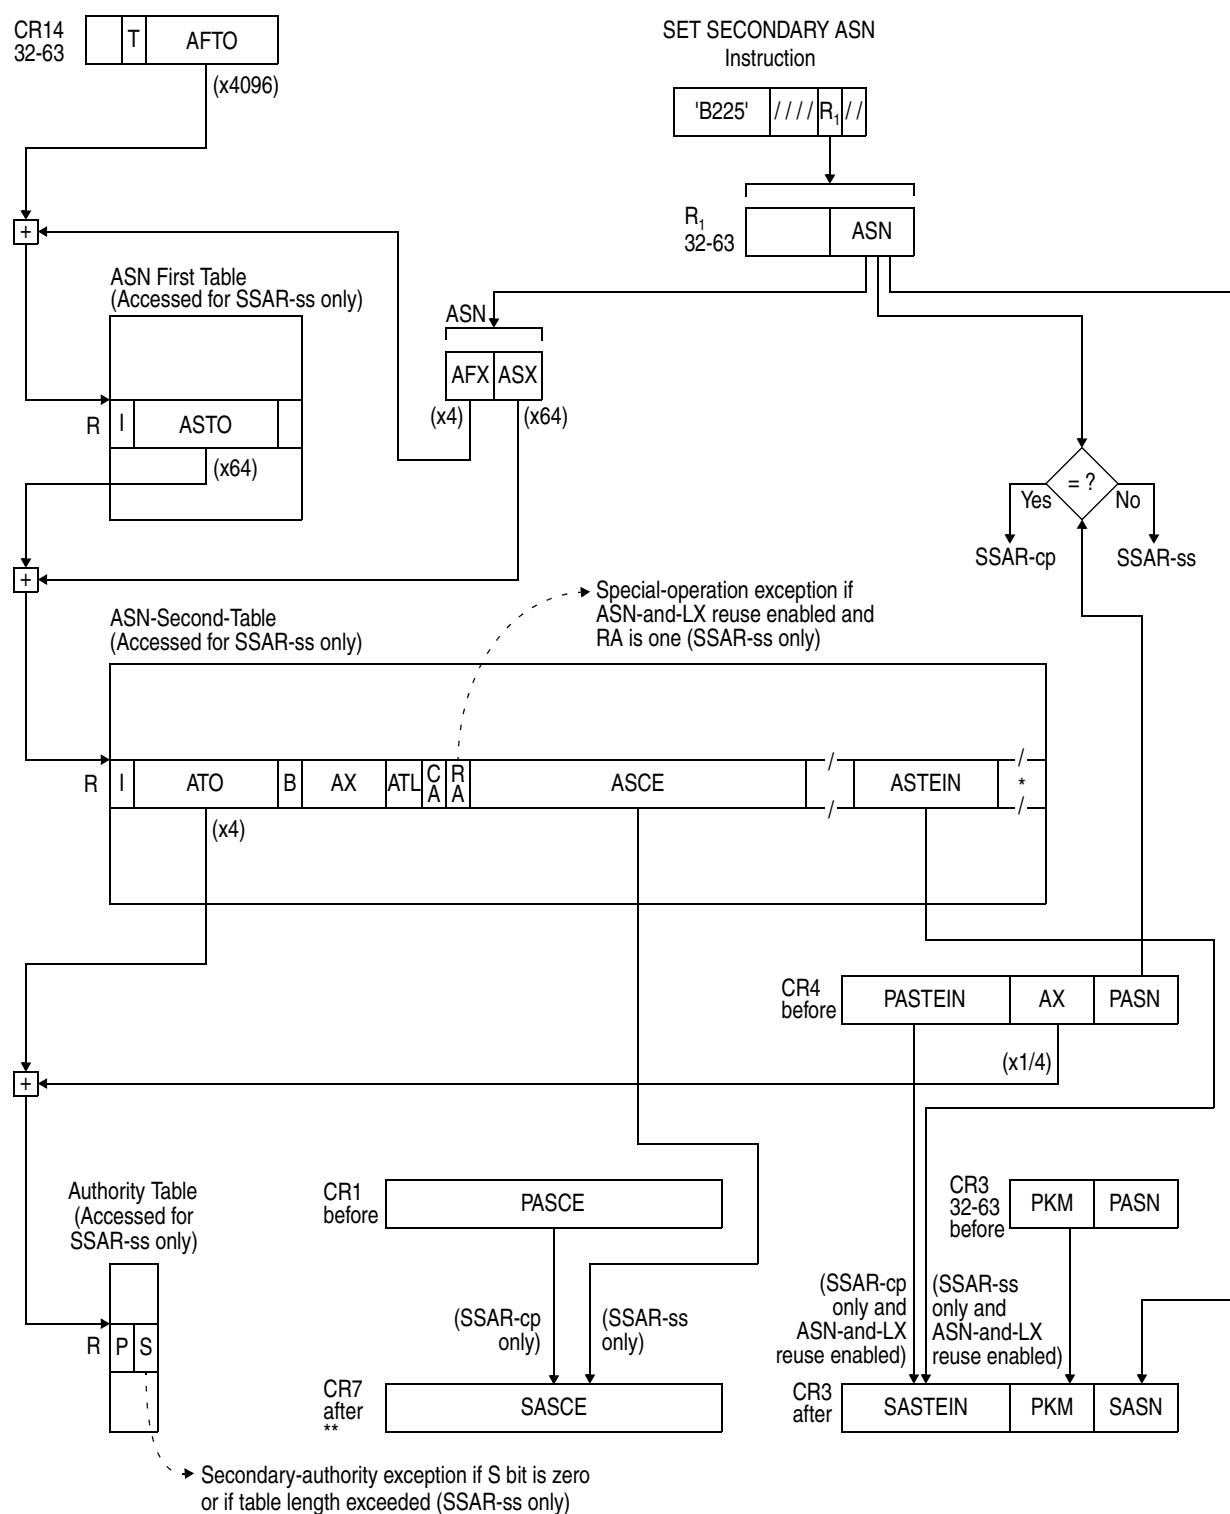

**Programming Note:** A program given control by a basic PROGRAM CALL operation can use EXTRACT SECONDARY ASN AND INSTANCE to obtain the ASTEIN to be used by PROGRAM TRANSFER WITH INSTANCE to return to the calling program or by SET SECONDARY ASN WITH INSTANCE to restore its secondary address space after a change of that space. This EXTRACT SECONDARY ASN AND INSTANCE instruction should be executed while the original secondary space remains continuously the secondary space; otherwise, depending on actions by the control program, EXTRACT SECONDARY ASN AND INSTANCE may return an ASTEIN that allows return to or use of a

conceptually incorrect secondary space for which the ASTEIN has been changed.

- 1.-6. Exceptions with the same priority as the priority of program-interruption conditions for the general case.
- 7.A Access exceptions for second instruction halfword.
- 7.B.1 Operation exception (SSAIR only, if the ASN-and-LX-reuse facility is not installed).
- 7.B.2 Special-operation exception due to DAT being off, or the ASN-translation control, bit 44 of control register 14, being zero.
- 8.A Trace exceptions.
- 8.B.1 ASN-translation exceptions (SSAR-ss and SSAIR-ss only).
- 8.B.2 Special-operation exception due to ASN-and-LX reuse enabled and reusable-ASN bit in ASN-second-table entry being one (SSAR-ss only).
- 8.B.3 Special-operation exception due to controlled-ASN bit in ASN-second-table entry being one in the problem state (SSAIR-ss only).
- 8.B.4 ASTE-instance exception due to ASTEIN in general register R<sub>1</sub> not being equal to ASTEIN in ASN-second-table entry (SSAIR-ss only).  
**Note:** Subspace-replacement exceptions, which are not shown in detail in this figure, can occur with any priority after 8.B.4.
- 8.B.5 Secondary-authority exception due to authority-table entry being outside table (SSAR-ss and SSAIR-ss only).
- 8.B.6 Addressing exception for access to authority-table entry (SSAR-ss and SSAIR-ss only).
- 8.B.7 Secondary-authority exception due to S bit in authority-table entry being zero (SSAR-ss and SSAIR-ss only).

Figure 10-57. Priority of Execution: SET SECONDARY ASN (WITH INSTANCE)

## SET SECONDARY ASN WITH INSTANCE

R: Address is real

\*: ASTE is 64 bytes; selected fields and the last 16 bytes are not shown.

\*\*: For SSAR-ss only, bits 0-55 and 58-63 of SASCE may be replaced from a subspace ASCE

Figure 10-58. Execution of SET SECONDARY ASN

## SET SECONDARY ASN WITH INSTANCE

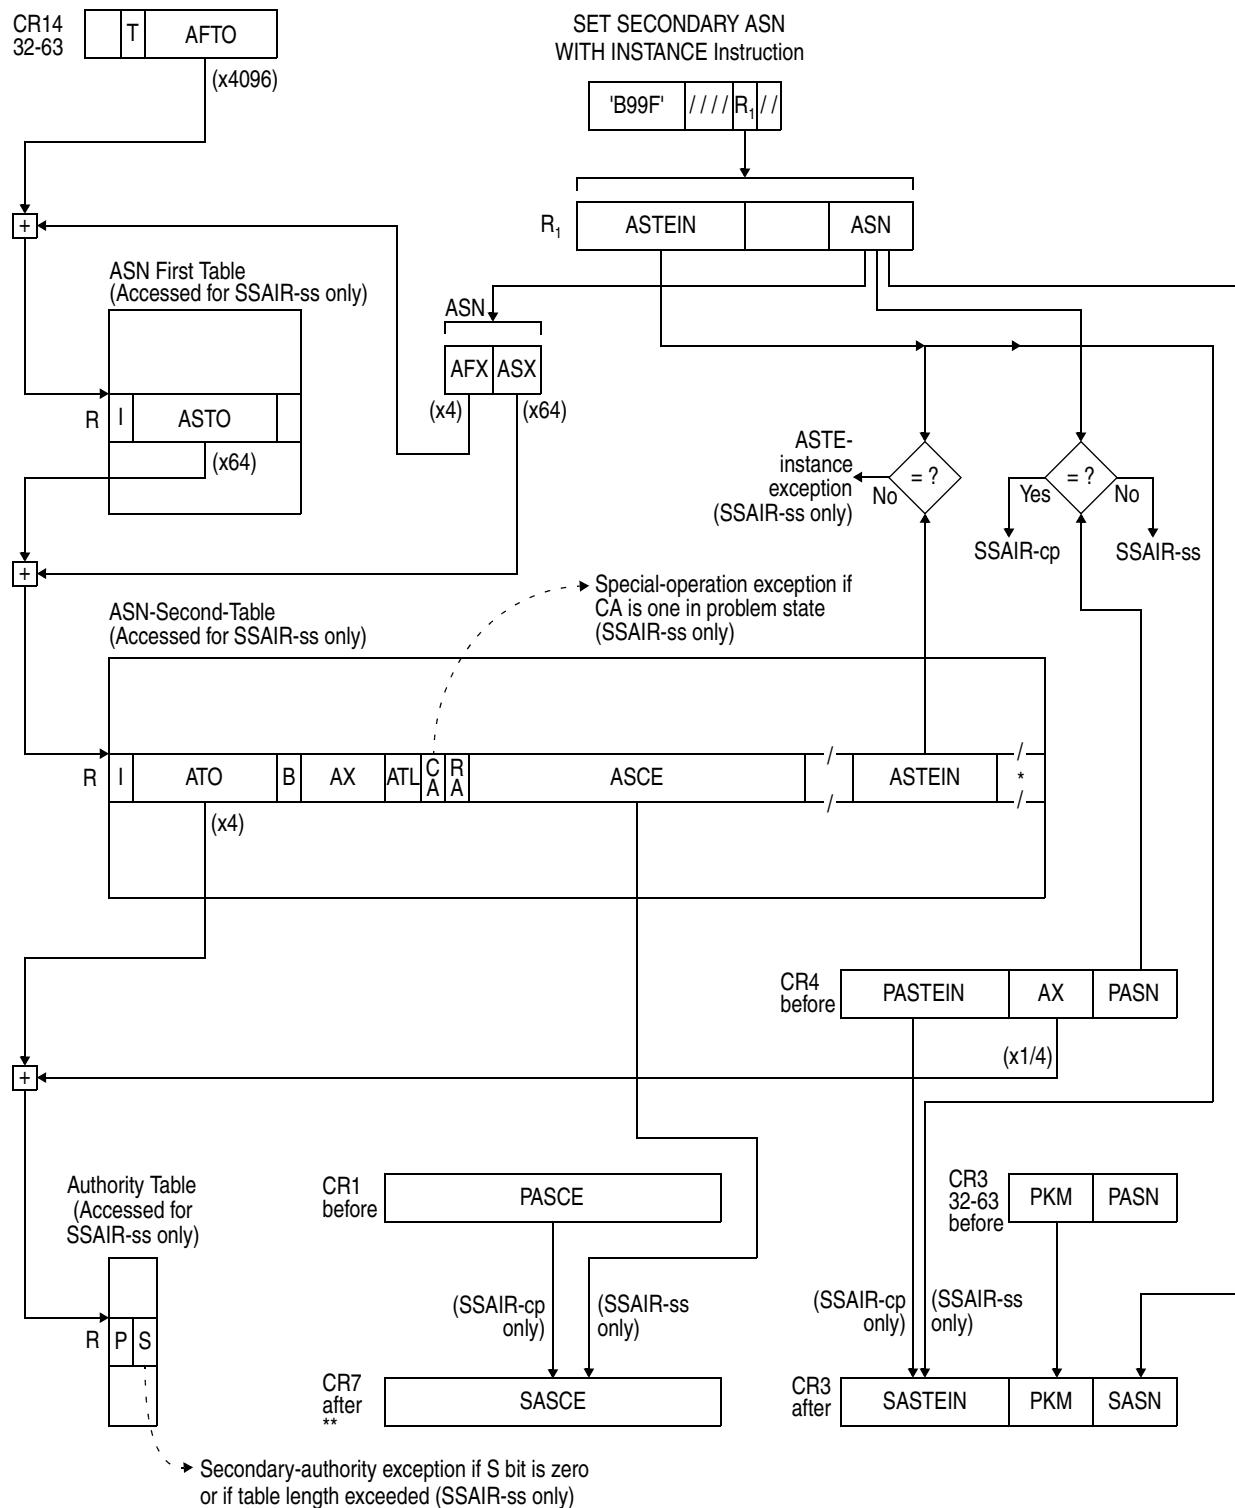

Figure 10-59. Execution of SET SECONDARY ASN WITH INSTANCE

## SET STORAGE KEY EXTENDED

SSKE	R <sub>1</sub> ,R <sub>2</sub> [M <sub>3</sub> ]	[RRF]
'B22B'	M <sub>3</sub>         R <sub>1</sub>   R <sub>2</sub>	16 20 24 28 31

The storage key for one or more 4K-byte blocks is replaced by the value in the first-operand register. When the conditional-SSKE facility is installed, certain functions of the key-setting operation may be bypassed.

When the conditional-SSKE facility is not installed, or when the conditional-SSKE facility is installed and both the MR and MC bits of the M<sub>3</sub> field are zero, the storage key for the 4K-byte block that is addressed by the contents of general register R<sub>2</sub> is replaced by bits from general register R<sub>1</sub>. The instruction completes without changing the condition code.

When the conditional-SSKE facility is installed and either or both of the MR and MC bits are one, the access-control bits, fetch-protection bit, and, optionally, the reference bit and change bit of the storage key that is addressed by the contents of general register R<sub>2</sub> are compared with corresponding bits in general register R<sub>1</sub>. If the compared bits are equal, then no change is made to the key; otherwise, selected bits of the key are replaced by the corresponding bits in general register R<sub>1</sub>. The storage key prior to any modification is inserted in general register R<sub>1</sub>, and the result is indicated by the condition code.

When the enhanced-DAT facility is installed, the above operations may be repeated for the storage keys of multiple 4K-byte blocks within the same 1MB block, subject to the control of the multiple-block control, described below.

The M<sub>3</sub> field has the following format:

The bits of the M<sub>3</sub> field are defined as follows:

- **Reserved:** Bit 0 is reserved.
- **Reference-Bit-Update Mask (MR):** The MR bit, bit 1 of the M<sub>3</sub> field, controls whether updates to the reference bit in the storage key may be bypassed, as described below.

the reference bit in the storage key may be bypassed, as described below.

- **Change-Bit-Update Mask (MC):** The MC bit, bit 2 of the M<sub>3</sub> field, controls whether updates to the change bit in the storage key may be bypassed, as described below.
- **Multiple-Block Control (MB):** The MB bit, bit 3 of the M<sub>3</sub> field, controls whether the storage keys for multiple 4K-byte blocks of storage may be set, as described in “Setting Storage Keys in Multiple 4K-Byte Blocks” on page 10-116.

When the conditional-SSKE facility is not installed, bit positions 1 and 2 of the M<sub>3</sub> field are reserved. When the enhanced-DAT facility is not installed, bit position 3 of the M<sub>3</sub> field is reserved. Reserved bit positions of the M<sub>3</sub> field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

When the conditional-SSKE facility is installed, processing is as follows:

1. When both the MR and MC bits, bits 1 and 2 of the M<sub>3</sub> field, are zero, the instruction completes as though the conditional-SSKE facility was not installed. The storage key for the 4K-byte block that is addressed by the contents of general register R<sub>2</sub> is replaced by bits from general register R<sub>1</sub>, and the instruction completes without changing the condition code.
2. When either or both the MR and MC bits are one, processing is as follows:
  - a. Prior to any modification, the contents of the storage key for the 4K-byte block that is addressed by general register R<sub>2</sub> are placed in bit positions 48-54 of general register R<sub>1</sub>, and bit 55 of general register R<sub>1</sub> is set to zero. Bits 0-47 and 56-63 of the register remain unchanged.

If an invalid checking-block code (CBC) is detected when fetching the storage key, then (a) the entire storage key for the 4K-byte block is replaced by bits 56-62 of general register R<sub>1</sub>, (b) the contents of bit positions 48-55 of general register R<sub>1</sub> are unpredictable, and (c) the instruction completes by setting condition code 3.

- b. The access-control bits and fetch-protection bit of the storage key for the designated 4K-byte block are compared with the corresponding fields in bits 56-60 of general register R<sub>1</sub>. If the respective fields are not equal, the entire storage key for the 4K-byte block is replaced by bits from general register R<sub>1</sub>, and the instruction completes by setting condition code 1.

When the access-control and fetch-protection bits in the storage key are equal to the respective bits in general register R<sub>1</sub>, processing continues as described below.

- c. When both the MR and MC bits are one, the instruction completes by setting condition code 0. The storage key remains unchanged in this case.
- d. When the MR bit is zero and the MC bit is one, then the reference bit of the storage key for the designated 4K-byte block is compared with bit 61 of general register R<sub>1</sub>. If the bits are equal, the instruction completes by setting condition code 0. The storage key remains unchanged in this case.

If the bits are not equal, then either (a) the entire storage key for the designated 4K-byte block is replaced by the bits in general register R<sub>1</sub>, and the instruction completes by setting condition code 1; or (b) the reference bit for the storage key is replaced by bit 61 of general register R<sub>1</sub>, the change bit for the key is unpredictable, and the instruction completes by setting condition code 2. It is unpredictable whether condition code 1 or 2 is set.

- e. When the MC bit is zero and the MR bit is one, then the change bit of the storage key for the designated 4K-byte block is compared with bit 62 of general register R<sub>1</sub>. If the bits are equal, the instruction completes by setting condition code 0. The storage key remains unchanged in this case, except that the reference bit is unpredictable.

If the bits are not equal, then either (a) the entire storage key for the designated 4K-byte block is replaced by the bits in general register R<sub>1</sub>, and the instruction completes by setting condition code 1; or (b) the change bit

for the storage key is replaced by bit 62 of general register R<sub>1</sub>, the reference bit for the key is unpredictable, and the instruction completes by setting condition code 2. It is unpredictable whether condition code 1 or 2 is set.

When the enhanced-DAT facility is not installed, or when the facility is installed but the multiple-block control is zero, general register R<sub>2</sub> contains a real address. When the enhanced-DAT facility is installed and the multiple-block control is one, general register R<sub>2</sub> contains an absolute address.

In the 24-bit addressing mode, bits 40-51 of general register R<sub>2</sub> designate a 4K-byte block in real or absolute storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R<sub>2</sub> designate a 4K-byte block in real or absolute storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R<sub>2</sub> designate a 4K-byte block in real or absolute storage, and bits 52-63 of the register are ignored.

Because it is a real or absolute address, the address designating the storage block is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The new seven-bit storage-key value, or selected bits thereof, is obtained from bit positions 56-62 of general register R<sub>1</sub>. The contents of bit positions 0-55 and 63 of the register are ignored. When the conditional-SSKE facility is installed, and either or both the MR and MC bits are one, bit position 63 should contain a zero; otherwise, the program may not operate compatibly in the future.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed, except that when the conditional-SSKE facility is installed and the resulting condition code is 0, it is unpredictable whether a serialization and checkpoint-synchronization function is performed after the operation completes.

For any store access, by any CPU or channel program, completed to the designated 4K-byte block either before or after the setting of the key by this instruction, the associated setting of the reference and change bits to one in the storage key for the

block also is completed before or after, respectively, the execution of this instruction.

### Setting Storage Keys in Multiple 4K-Byte Blocks

When the enhanced-DAT facility is not installed, or when the facility is installed, but the multiple-block control is zero, the storage key for a single 4K-byte block is set, as described above.

When the enhanced-DAT facility is installed, and the multiple-block control is one, the storage keys for multiple 4K-byte blocks within a 1M-byte block may be set, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 1M-byte boundary. In this case, SET STORAGE KEY EXTENDED is interruptible, and processing is as follows:

- When an interruption occurs (other than one that follows termination), the leftmost bits of general register  $R_2$  comprising the 4K-byte block address have been updated so the instruction, when reexecuted, resumes at the point of interruption. If either or both the MR or MC bits are one, the condition code is unpredictable; otherwise, the condition code is unchanged.
- When the instruction completes without interruption, the leftmost bits of general register  $R_2$  comprising the 4K-byte block address have been updated to the next 1M-byte boundary. If either or both the MR or MC bits are one, condition code 3 is set; otherwise, the condition code is unchanged.

In either of the above two cases, the following applies:

- Bits 52-63 of general register  $R_2$  remain unchanged.
- When either or both the MR or MC bits are one, bits 48-55 of general register  $R_1$  are unpredictable.

When multiple-block processing occurs and the  $R_1$  and  $R_2$  fields designate the same register, the second-operand address is placed in the register. When multiple-block processing occurs in the 24-bit or 31-bit addressing modes, the leftmost bits which are not part of the address in bit positions 32-63 of general register  $R_2$  are set to zeros; bits 0-31 of the register are unchanged.

### **Resulting Condition Code:**

When the conditional-SSKE facility is not installed, or when both the MR and MC bits of the  $M_3$  field are zero, the condition code remains unchanged.

When the conditional-SSKE facility is installed, and either or both of the MR and MC bits are one, the condition code is set as follows:

- 0 Storage key not set
- 1 Entire storage key set
- 2 Partial storage key set
- 3 Entire storage key set; bits 48-55 of general register  $R_1$  are unpredictable.

### **Program Exceptions:**

- Addressing (address specified by general register  $R_2$ )
- Privileged operation

### **Programming Notes:**

1. The  $M_3$  field of the instruction is considered to be optional, as indicated by the field being contained within brackets [] in the assembler syntax. When the  $M_3$  field is not specified, the assembler places zeros in that field of the instruction.
2. When setting multiple storage keys within the same 1M-byte block to the same value, use of the multiple-block control (MB, bit 3 of the  $M_3$  field) may yield better performance than executing separate SSKE instructions for each 4K-byte block in the megabyte.
3. As stated in the definition of the  $M_3$  field on page 10-114, reserved bit positions should generally contain zeros; otherwise the program may not operate compatibly in the future. However, if the program does not rely on the setting of the reference bit, it may set the MR bit of the  $M_3$  field to one, regardless of whether or not the conditional-SSKE facility is installed. Similarly, if the program does not rely on the setting of the change bit, it may set the MC bit of the  $M_3$  field to one, regardless of whether or not the conditional-SSKE facility is installed. In these cases, the program cannot rely on the condition code or the key value returned in general register  $R_1$ . Conversely, if the program depends on accurate setting of the reference or change bit, then the MR and MC bits should be set to zero, such that reference

and change bit recording are properly maintained when the conditional-SSKE facility is installed.

## SET SYSTEM MASK

SSM	D <sub>2</sub> (B <sub>2</sub> )	[S]
'80'	B <sub>2</sub>	D <sub>2</sub>

Bits 0-7 of the current PSW are replaced by the byte at the location designated by the second-operand address.

### Special Conditions

When the SSM-suppression-control bit, bit 33 of control register 0, is one and the CPU is in the supervisor state, a special-operation exception is recognized.

The value to be loaded into the PSW is not checked for validity before loading. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, if the contents of bit positions 0 and 2-4 of the PSW are not all zeros. In this case, the instruction is completed, and the instruction-length code is set to 2. The specification exception, which is listed as a program exception for this instruction, is described in "Early Exception Recognition" on page 6-8. This exception may be considered as caused by execution of this instruction or as occurring early in the process of preparing to execute the subsequent instruction.

The operation is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Special operation
- Specification

## SIGNAL PROCESSOR

SIGP	R <sub>1</sub> ,R <sub>3</sub> ,D <sub>2</sub> (B <sub>2</sub> )	[RS]
'AE'	R <sub>1</sub> R <sub>3</sub> B <sub>2</sub>	D <sub>2</sub>

An eight-bit order code and, if called for, a 32-bit parameter are transmitted to the CPU designated by the CPU address contained in the third operand. The result is indicated by the condition code and may be detailed by status assembled in bit positions 32-63 of the first-operand location.

The second-operand address is not used to address data; instead, bits 56-63 of the address contain the eight-bit order code. Bits 0-55 of the second-operand address are ignored. The order code specifies the function to be performed by the addressed CPU. The assignment and definition of order codes appear in "CPU Signaling and Response" on page 4-57.

The 16-bit binary number contained in bit positions 48-63 of general register R<sub>3</sub> forms the CPU address. Bits 0-47 of the register are ignored. When the specified order is the set-architecture order, the CPU address is ignored; all other CPUs in the configuration are considered to be addressed.

The general register containing the 32-bit parameter in bit positions 32-63 is R<sub>1</sub> or R<sub>1</sub>+1, whichever is the odd-numbered register. It depends on the order code whether a parameter is provided and for what purpose it is used.

The operands just described have the following formats:

General register designated by R<sub>1</sub>:

0
31

Status
32
63

General register designated by R<sub>1</sub> or R<sub>1</sub>+1, whichever is the odd-numbered register:

0
31

Parameter
32
63

General register designated by R<sub>3</sub>:

0	31
32	48

CPU Address

#### Programming Notes:

1. A more detailed discussion of the condition-code settings for SIGNAL PROCESSOR is contained in "CPU Signaling and Response" on page 4-57.
2. To ensure that presently written programs will be executed properly when new facilities using additional bits are installed, only zeros should appear in the unused bit positions of the second-operand address and in bit positions 32-47 of general register R<sub>3</sub>.
3. Certain SIGNAL PROCESSOR orders are provided with the expectation that they will be used primarily in special circumstances. Such orders may be implemented with the aid of an auxiliary maintenance or service processor, and, thus, the execution time may take several seconds. Unless all of the functions provided by the order are required, combinations of other orders, in conjunction with appropriate programming support, can be expected to provide a specific function more rapidly. The emergency-signal, external-call, and sense orders are the only orders which are intended for frequent use. The following orders are intended for infrequent use, and performance therefore may be much slower than for frequently used orders: restart, set prefix, store status at address, start, stop, stop and store status, set architecture, and all the reset orders. An alternative to the set-prefix order, for faster performance when the receiving CPU is not already stopped, is the use of the emergency-signal or external-call order, followed by the execution of a SET PREFIX instruction on the addressed CPU. Clearing the TLB of entries is ordinarily accomplished more rapidly through the use of the emergency-signal or external-call order, followed by execution of the PURGE TLB instruction on the addressed CPU, than by use of the set-prefix order.

Second-operand address:

0	31
32	56

Order Code

A serialization function is performed before the operation begins and again after the operation is completed.

When the order code is accepted and no nonzero status is returned, condition code 0 is set. When status information is generated by this CPU or returned by the addressed CPU, the status is placed in bit positions 32-63 of general register R<sub>1</sub>, bits 0-31 of the register remain unchanged, and condition code 1 is set.

When the access path to the addressed CPU is busy, or the addressed CPU is operational but in a state where it cannot respond to the order code, condition code 2 is set.

When the addressed CPU is not operational (that is, it is not provided in the installation, it is not in the configuration, it is in any of certain customer-engineer test modes, or its power is off), condition code 3 is set.

#### Resulting Condition Code:

- 0 Order code accepted
- 1 Status stored
- 2 Busy
- 3 Not operational

#### Program Exceptions:

- Privileged operation

## STORE CLOCK COMPARATOR

STCKC	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B207'	B <sub>2</sub>

The current value of the clock comparator is stored at the doubleword location designated by the second-operand address.

Zeros are provided for the rightmost bit positions of the clock comparator that are not compared with the TOD clock.

### Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification

## STORE CONTROL

STCTL	R <sub>1</sub> ,R <sub>3</sub> ,D <sub>2</sub> (B <sub>2</sub> )	[RS]
'B6'	R <sub>1</sub>	R <sub>3</sub>

0            8            12            16            20            31

STCTG	R <sub>1</sub> ,R <sub>3</sub> ,D <sub>2</sub> (B <sub>2</sub> )	[RSY]
'EB'	R <sub>1</sub>	R <sub>3</sub>

0            8            12            16            20            32            40            47

Bits of the set of control registers starting with control register R<sub>1</sub> and ending with control register R<sub>3</sub> are stored at the locations designated by the second-operand address.

For STORE CONTROL (STCTL), bits 32-63 of the control registers are stored in successive words beginning at the second-operand address, and bits 0-31 of the registers are ignored. For STORE CONTROL (STCTG), bits 0-63 of the control registers are stored in successive doublewords beginning at the second-operand address.

The storage area where the contents of the control registers are placed starts at the location designated by the second-operand address and continues through as many storage words, for STCTL, or doublewords, for STCTG, as the number of control registers specified. The contents of the control registers are stored in ascending order of their register num-

bers, starting with control register R<sub>1</sub> and continuing up to and including control register R<sub>3</sub>, with control register 0 following control register 15. The contents of the control registers remain unchanged.

The displacement for STCTL is treated as a 12-bit unsigned binary integer. The displacement for STCTG is treated as a 20-bit signed binary integer.

### Special Conditions

The second operand must be designated on a word boundary for STCTL or on a doubleword boundary for STCTG; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification

## STORE CPU ADDRESS

STAP	D <sub>2</sub> (B <sub>2</sub> )	[S]
'B212'	B <sub>2</sub>	D <sub>2</sub>

0            16            20            31

The CPU address by which this CPU is identified in a multiprocessing configuration is stored at the halfword location designated by the second-operand address.

### Special Conditions

The operand must be designated on a halfword boundary; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification

# STORE CPU ID

STIDP	$D_2(B_2)$	[S]
'B202'	$B_2$	$D_2$
0	16	20

Information identifying either (1) the CPU or (2) the configuration and the logical partition in which the program is being executed is stored at the double-word location designated by the second-operand address.

The information stored has the following format:

Bit positions 8-31 contain the CPU identification number, consisting of six four-bit digits. Some or all of these digits are selected from the physical serial number stamped on the CPU.

The format bit (F) in bit position 48 specifies the format of the first two digits of the CPU identification number.

When the format bit is zero, the contents of the CPU-identification-number field, in conjunction with the machine-type number, permit unique identification of the CPU. When the format bit is one, the CPU-identification number identifies the system configuration as opposed to an individual CPU within the configuration, and it identifies the logical partition in which the program is being executed.

Bit positions 32-47 contain the machine-type number of the CPU. Bit positions 0-7 and 49-63 contain zeros.

### **Special Conditions**

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

## ***Program Exceptions:***

- Access (store, operand 2)

- Privileged operation
  - Specification

## Programming Notes:

1. The program should allow for the possibility that the CPU identification number may contain the digits A-F as well as the digits 0-9.
  2. When the format bit in bit position 48 of the second operand is zero, the CPU identification number, in conjunction with the machine-type number, provides a unique CPU identification that can be used in associating results with an individual machine.

When the format bit is one, the CPU-identification number identifies the system configuration as opposed to an individual CPU within the configuration, and it identifies the requesting logical partition. The CPU identity can be obtained using the STORE CPU ADDRESS or the STORE SYSTEM INFORMATION instruction.

3. In versions of *Enterprise Systems Architecture/390 Principles of Operation* prior to SA22-7201-03, the machine-type-number field was called the model-number field.
  4. In ESA/390, bit positions 0-7 of the information stored contain a version code. When the version code is nonzero, it is usually indicative of the model number of the model and the number of CPUs contained in the model. In both ESA/390 and z/Architecture, the STORE SYSTEM INFORMATION instruction can be used to determine the model number and the number of CPUs in the model.
  5. The CPU identification number has the hex format:
    - “Annnnn” in the basic mode, or
    - LPnnnn” in the LPAR (logically-partitioned) mode, when the format bit is zero, or
    - PPnnnn” in the LPAR mode, when the format bit is one.

Where:

- A is the CPU address of the CPU.
  - L is a logical CPU address.
  - P is a logical-partition identifier.
  - PP is the user partition identifier (UPID). The UPID is an eight-bit unsigned binary integer bound to a logical partition.

- n is a digit derived from the serial number of the CPU.

The terminology above that is not defined in this publication is defined in the appropriate System Library publications for the model.

6. The format bit is always stored as a zero in the basic mode.
7. Model z800 and z900 machines always store the format bit as a zero.
8. When STORE CPU ID is executed in a virtual machine, the VM operating system replaces bits 0-7 of the information stored with FF hex.

## STORE CPU TIMER

STPT	D <sub>2</sub> (B <sub>2</sub> )	[S]
	'B209'	B <sub>2</sub>
0	16	20

31

The current value of the CPU timer is stored at the doubleword location designated by the second-operand address.

Zeros are provided for the rightmost bit positions that are not updated by the CPU timer.

### Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification

## STORE FACILITY LIST

STFL	D <sub>2</sub> (B <sub>2</sub> )	[S]
	'B2B1'	B <sub>2</sub>
0	16	20

31

A list of bits providing information about facilities is stored in the word at real address 200. The meanings of the bits are identical to the first 32 bits stored by STORE FACILITY LIST EXTENDED. Figure 4-18, "Assigned Facility Bits" on page 4-65 shows the meanings of the assigned facility bits.

The second-operand address is ignored but should be zero to permit possible future extensions.

Key-controlled and low-address protection do not apply.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Privileged operation

**Programming Note:** STORE FACILITY LIST stores only a 32-bit indication of facilities. STORE FACILITY LIST EXTENDED may be used to store the entire list of installed facilities.

## STORE PREFIX

STPX	D <sub>2</sub> (B <sub>2</sub> )	[S]
	'B211'	B <sub>2</sub>
0	16	20

31

The contents of bit positions 33-50 of the prefix register are stored in bit positions 1-18 of the word location designated by the second-operand address, and zeros are stored in bit positions 0 and 19-31 of the word.

### Special Conditions

The operand must be designated on a word boundary; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification

## STORE REAL ADDRESS

STRAG	D <sub>1</sub> (B <sub>1</sub> ),D <sub>2</sub> (B <sub>2</sub> )	[SSE]				
	'E502'	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>	
0		16	20	32	36	47

The 64-bit real address corresponding to the second-operand virtual address is stored in the doubleword at the location designated by the first-operand address.

The virtual address specified by the B<sub>2</sub> and D<sub>2</sub> fields is translated by means of the dynamic-address-translation facility, regardless of whether DAT is on or off.

DAT is performed by using an address-space-control element that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW, as shown in the following table:

PSW	
Bits 16 and 17	Address-Space-Control Element Used by DAT
00	Contents of control register 1
10	Contents of control register 7
01	The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the B <sub>2</sub> field
11	Contents of control register 13

ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively.

The resultant 64-bit real address is stored at the first-operand location.

The translated address is not inspected for boundary alignment or for addressing or protection exceptions.

The address computations for the operands are performed according to the current addressing mode, specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry are treated as 64-bit addresses regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

### Special Conditions

The first operand must be designated on a double-word boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing exceptions.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch, operand 2, except for an addressing or protection exception for the designated location; store, operand 1)
- Privileged operation
- Specification

**Programming Note:** STORE REAL ADDRESS is contrasted to LOAD REAL ADDRESS as follows:

- In the 24-bit or 31-bit addressing mode, LOAD REAL ADDRESS (LRA) loads bits 33-63 of the real address if bits 0-32 of the address are all zeros or recognizes a special-operation exception if bits 0-32 are not all zeros. LRA in the 64-bit addressing mode, and LOAD REAL ADDRESS (LRAG) in any addressing mode, loads bits 0-63 of the real address. STORE REAL ADDRESS stores bits 0-63 of the real address in any addressing mode.
- LOAD REAL ADDRESS, for most access-exception conditions, does not recognize the conditions as exceptions but instead sets the condition code to indicate the occurrence of the conditions. STORE REAL ADDRESS recognizes all access-exception conditions as exceptions, resulting in a program interruption.

## STORE SYSTEM INFORMATION

STSI	D <sub>2</sub> (B <sub>2</sub> )	[S]		
	'B27D'	B <sub>2</sub>	D <sub>2</sub>	
0		16	20	31

Depending on a function code in general register 0, either an identification of the level of the configuration executing the program is placed in general register 0 or information about a component or components of a configuration is stored in a system-information

block (SYSIB). When information about a component or components is requested, the information is specified by further contents of general register 0 and by contents of general register 1. The SYSIB, if any, is designated by the second-operand address.

The machine is considered to provide one, two, or three levels of configuration. The levels are:

1. The basic machine, which is the machine as if it were operating in the basic mode.
2. A logical partition, which is provided if the machine is operating in the LPAR, or logically-partitioned, mode. A logical partition is provided by the LPAR hypervisor, which is a part of the machine. A basic machine exists even when the machine is operating in the LPAR mode.
3. A virtual machine, which is provided by a virtual-machine (VM) control program that is executed either by the basic machine or in a logical partition. A virtual machine may itself execute a VM control program that provides a higher-level (more removed from the basic machine) virtual machine, which also is considered a level-3 configuration.

The terms basic mode, LPAR mode, logical partition, hypervisor, and virtual machine, and any other terms related specifically to those terms, are not defined in this publication; they are defined in the machine manuals.

A program being executed by a level-1 configuration (the basic machine) can request information about that configuration. A program being executed by a level-2 configuration (in a logical partition) can request information about the logical partition and about the underlying basic machine. A program being executed by a level-3 configuration (a virtual machine) can request information about the virtual machine and about the one or two underlying levels; a basic machine is always underlying, and a logical partition may or may not be between the basic machine and the virtual machine. When information about a virtual machine is requested, information is provided about the configuration executing the program and about any underlying level or levels of virtual machine. In any of these cases, information is provided about a level only if the level implements the instruction.

The function code determining the operation is an unsigned binary integer in bit positions 32-35 of general register 0 and is as follows:

Function Code	Information Requested
0	Current-configuration-level number
1	Information about level 1 (the basic machine)
2	Information about level 2 (a logical partition)
3	Information about level 3 (a virtual machine)
4-14	None; codes are reserved
15	Current-configuration-level information

#### Invalid Function Code

The level of the configuration executing the program is called the current level. The configuration level specified by a nonzero function code is called the specified level. When the specified level is numbered higher than the current level, then the function code is called invalid, the condition code is set to 3, and no other action (including checking) is performed.

#### Valid Function Code

When the function code is equal to or less than the number of the current level, or 15, it is called valid. In this case, bits 36-55 of general register 0 and bits 32-47 of general register 1 must be zero; otherwise, a specification exception is recognized. Bits 0-31 of general registers 0 and 1 always are ignored.

When the function code is 0, an unsigned binary integer identifying the current configuration level (1 for basic machine, 2 for logical partition, or 3 for virtual machine) is placed in bit positions 32-35 of general register 0, the condition code is set to 0, and no further action is performed.

When the function code is valid and nonzero, general registers 0 and 1 contain additional specifications about the information requested, as follows:

- Bit positions 56-63 of general register 0 contain an unsigned binary integer, called *selector 1*, that specifies a component or components of the specified configuration.
- Bit positions 48-63 of general register 1 contain an unsigned binary integer, called *selector 2*, that specifies the type of information requested.

The contents of general registers 0 and 1 are as follows:

#### General Register 0

0	FC	0 0	31	36	56	63
---	----	---	----	----	----	----

#### General Register 1

0	0 0	31	48	63
---	---	----	----	----

When the function code is valid and nonzero, information may be stored in a system-information block (SYSIB) beginning at the second-operand location. The SYSIB is 4K bytes and must begin at a 4K-byte boundary; otherwise, a specification exception may be recognized, depending on selector 1 and selector 2 and on whether access exceptions are recognized due to references to the SYSIB (see “Special Conditions”).

Selector 1 can have values as follows:

#### Selector 1 Information Requested

0	None; selector is reserved
1	Information about the configuration level specified by the function code.
2	Information about one or more CPUs in the specified configuration level
3-255	None; selectors are reserved

When selector 1 is 1, selector 2 can have values as follows:

#### Selector 2

when

#### Selector 1

Is 1	Information Requested
0	None; selector is reserved
1	Information about the specified configuration level
2	Topology information about the specified configuration level
3-65,535	None; selectors are reserved

When selector 1 is 2, selector 2 can have values as follows:

#### Selector 2

when

#### Selector 1 Is

2	Information Requested
0	None; selector is reserved
1	Information about the CPU executing the program in the specified configuration level
2	Information about all CPUs in the specified configuration level
3-65,535	None; selectors are reserved

Only certain combinations of the function code, selector 1, and selector 2 are valid, as shown in Figure 10-60.

Func- tion Code	Selec- tor 1	Selec- tor 2	Information Requested about
0	-	-	Current-configuration-level number
1	1	1	Basic-machine configuration
1	2	1	Basic-machine CPU
1	2	2	Basic-machine CPUs
2	2	1	Logical-partition CPU
2	2	2	Logical-partition CPUs
3	2	2	Virtual-machine CPUs
15	1	2	Topology information of current configuration

#### Explanation:

- Ignored.

Figure 10-60. Valid Function-Code, Selector-1, and Selector-2 Combinations for STORE SYSTEM INFORMATION

When the specified function-code, selector-1, and selector-2 combination is invalid (is other than as shown in Figure 10-60), or if it is valid but the requested information is not available because the specified level does not implement or does not fully implement the instruction or because a necessary part of the level is uninstalled or not initialized, and provided that an exception is not recognized (see “Special Conditions”), the condition code is set to 3. When the function code is nonzero, the combination is valid, the requested information is available, and there is no exception, the requested information is stored in a system-information block (SYSIB) at the second-operand address.

Some or all of the SYSIB may be fetched before it is stored.

A SYSIB may be identified in references by means of "SYSIB fc.s1.s2," where "fc," "s1," and "s2" are the values of a function code, selector 1, and selector 2, respectively.

Following sections describe the defined SYSIBs by means of figures and related text. In the figures, the offsets shown on the left are word values. "The configuration" refers to the configuration level specified by the function code (the configuration level about which information is requested).

### SYSIB 1.1.1 (Basic-Machine Configuration)

SYSIB 1.1.1 has the following format:

SYSIB 1.1.1

0	P	Reserved	Reserved
1		Reserved	
8		Manufacturer	
12		Type	
13		Reserved	
16		Model-Capacity Identifier	
20		Sequence Code	
24		Plant of Manufacture	
25		Model	
29		Model-Permanent-Capacity Identifier	
33		Model-Temporary-Capacity Identifier	

37	Model-Capacity Rating				
38	Model-Permanent-Capacity Rating				
39	Model-Temporary-Capacity Rating				
40	Type 1 Pctg.	Type 2 Pctg.	Type 3 Pctg.	Type 4 Pctg.	
41	Type 5 Pctg.	Reserved			
42	Reserved				
1023	0	8	16	24	31

**Word 0, Byte 0:** Byte 0 of word 0 contains the following bit definitions:

#### Bit Meaning

- 0 When bit 0 of byte 0 (P) is one, the type-percentage bytes, located in words 40-41 are valid. When P is zero, the bytes are stored as zeros, but have no meaning.
- 1-7 Bits 1-7 of byte 0 are reserved and stored as zeros.

**Reserved:** The contents of bytes 1-3 of word 0, words 1-7, 13-15, and 42-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

**Manufacturer:** Words 8-11 contain the 16-character (0-9 or uppercase A-Z) EBCDIC name of the manufacturer of the configuration. The name is left justified with trailing blanks if necessary.

**Type:** Word 12 contains the four-character (0-9) EBCDIC type number of the configuration. (This is called the machine-type number in the definition of STORE CPU ID.)

**Model-Capacity Identifier:** Words 16-19 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-capacity identifier of the configuration. The model-capacity identifier is left justified with trailing blanks if necessary.

**Sequence Code:** Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The sequence code is right justified with leading EBCDIC zeros if necessary.

**Plant of Manufacture:** Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

**Model:** When word 25 is not binary zeros, words 25-28 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model identification of the configuration. The model identification is left justified with trailing blanks if necessary. (This is called the model number in programming note 4 on page 10-120 of STORE CPU ID.) When word 25 is binary zeros, the contents of words 16-19 represent both the model-capacity identifier and the model.

**Model-Permanent-Capacity Identifier (P):** When non-zero, words 29-32 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-permanent-capacity identifier of the configuration. The identifier is left justified with trailing blanks if necessary.

**Model-Temporary-Capacity Identifier (T):** When non-zero, words 33-36 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-temporary-capacity identifier of the configuration. The identifier is left justified with trailing blanks if necessary.

**Model-Capacity Rating (CR):** When non-zero, word 37 contains a 32-bit unsigned integer whose value is associated with the model capacity as identified by the model-capacity identifier. There is no formal description of the algorithm used to generate this integer.

**Model-Permanent-Capacity Rating (PR):** When non-zero, word 38 contains a 32-bit unsigned integer whose value is associated with the model-permanent capacity as identified by the model-permanent-capacity identifier. There is no formal description of the algorithm used to generate this integer.

**Model-Temporary-Capacity Rating (TR):** When non-zero, word 39 contains a 32-bit unsigned integer whose value is associated with the model-temporary capacity as identified by the model-temporary-capacity identifier. There is no formal description of the algorithm used to generate this integer.

**Type N Pctg.** Each of the byte fields in words 40-41 that is designated as a type-N percentage contains an 8-bit unsigned binary integer whose value is in the range 0-100 and represents a percentage. When non-zero, the percentage may be used to affect the

use and allowed utilization of the secondary-CPUs whose CPU type corresponds to the particular byte. When a byte in this range contains a value of zero, use rules of the corresponding secondary-CPU type are not overridden. The reserved bytes in word 41 are reserved for the potential addition of new secondary CPU types.

### Programming Notes:

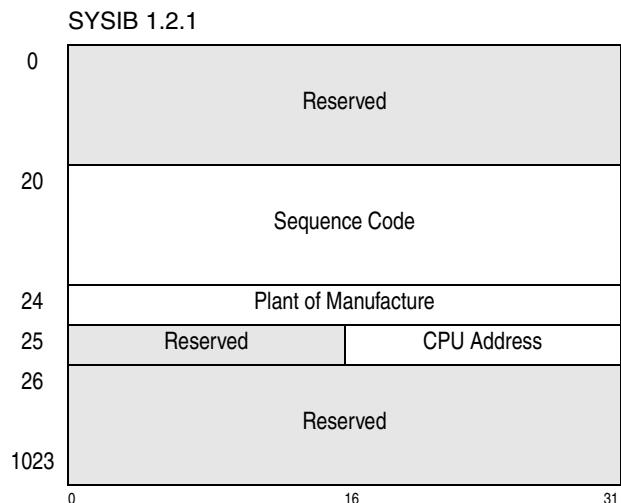

1. The fields of the SYSIB 1.1.1 are similar to those of the node descriptor described in the publication *Common I/O-Device Commands and Self Description*, SA22-7204. However, the contents of the SYSIB fields may not be identical to the contents of the corresponding node-descriptor fields because the SYSIB fields:
  - Allow more characters.
  - Are more flexible regarding the type of characters allowed.
  - Provide information that is justified differently within the field.
  - May not use the same method to determine the contents of fields such as the sequence-code field.
2. The model field in a node descriptor corresponds to the content of the STSI model field and not the STSI model-capacity-identifier field.
3. The model field specifies the model of the machine (i.e., the physical model); the model-capacity identifier field specifies a token that may be used to locate a statement of capacity or performance in the System Library publication for the model.
4. Each of the three model-capacity-identifier fields specifies a token that may be used to locate a statement of capacity or performance in the System Library publication for the model.
5. Each of the three model-capacity-rating fields, corresponding one-to-one with the three model-capacity-identifier fields, specifies a numeric value that may or may not represent the actual capacity of the machine.
6. The term *capacity backup* (CBU) represents a methodology by which spare capacity in a CPC can be used to replace capacity from another CPC within an enterprise, normally for a relatively limited period of time. Typically CBU is

used when another CPC of the enterprise has failed, and the CPC operating under CBU rules is making up for the missing CPC's capacity. However, CBU can also indicate a capacity that reflects a net reduction such that the current capacity would be less than the permanent capacity.

7. The term *On/Off Capacity on Demand* (On/Off CoD) represents a methodology by which spare capacity in a CPC can be made available to increase the total capacity within an enterprise, normally for a limited period of time. For example, On/Off CoD may be used to acquire additional capacity in order to handle a workload peak.
8. The content of the model-capacity identifier (C) field corresponds to the current capacity at which the central-processing complex (CPC) is operating.
9. The content of the model-permanent-capacity identifier (P) corresponds to the capacity of the CPC exclusive of temporarily-available increased capacity and temporarily-available replacement capacity.
10. The content of the model-temporary-capacity identifier (T) corresponds to the total of permanent capacity and temporarily-available increased capacity but exclusive of any temporarily-available replacement capacity.

### SYSIB 1.2.1 (Basic-Machine CPU)

SYSIB 1.2.1 has the following format:

0

16

31

**Reserved:** The contents of words 0-19, bytes 0 and 1 of word 25, and words 26-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

**Sequence Code:** Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The code is right justified with leading EBCDIC zeros if necessary.

**Plant of Manufacture:** Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

**CPU Address:** Bytes 2 and 3 of word 25 contain the CPU address by which this CPU is identified in a multiprocessing configuration. The CPU address is a 16-bit unsigned binary integer.

The CPU address is the same as is stored by STORE CPU ADDRESS when the program is executed by a machine operating in the basic mode.

**Programming Note:** Multiple CPUs in the same configuration have the same sequence code, and it is necessary to use other information, such as the CPU address, to establish a unique CPU identity. The sequence code returned for a basic-machine CPU and a logical-partition CPU are identical and have the same value as the sequence code returned for the basic-machine configuration.

### SYSIB 1.2.2 (Basic-Machine CPUs)

The format field in byte 0 of word 0 determines the format of the SYSIB.

When the format field has a value of zero, SYSIB 1.2.2 has a format-0 layout as follows:

Format-0 SYSIB 1.2.2

0	Format	Reserved
1		Reserved
7		Secondary CPU Capability

0 8 16 31

8	CPU Capability		
9	Total CPU Count	Configured CPU Count	
10	Standby CPU Count	Reserved CPU Count	
11	Multiprocessing CPU-Capability Adjustment Factors		
1023			
0	8	16	31

When the format field has a value of one, SYSIB 1.2.2 has a format-1 layout as follows:

Format-1 SYSIB 1.2.2

0	Format	Reserved	ACC Offset
1	Reserved		
7	Secondary CPU Capability		
8	CPU Capability		
9	Total CPU Count	Configured CPU Count	
10	Standby CPU Count	Reserved CPU Count	
11	Multiprocessing CPU-Capability Adjustment Factors		
N	Alternate CPU Capability		
N+1	Alternate Multiprocessing CPU-Capability Adjustment Factors		
1023			
0	8	16	31

**Reserved:** When the format field contains a value of zero, the contents of bytes 1-3 of word 0 and words 1-6 are reserved and stored as zeros. When the format field contains a value of one, the contents of byte 1 of word 0 and words 1-6 are reserved and stored as zeros.

When fewer than 64 words are needed to contain the information for all the CPUs, the portion of the SYSIB following the adjustment-factor list in a format-0 SYSIB or the alternate-adjustment-factor list in a format-1 SYSIB, up to word 63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

When 64 or more words are needed to contain the information for all the CPUs, the portion of the SYSIB

following the adjustment-factor list in a format-0 SYSIB or the alternate-adjustment-factor list in a format-1 SYSIB, up to word 1023 are reserved and may be stored as zeros or may remain unchanged.

**Format:** Byte 0 of word 0 contains an 8-bit unsigned binary integer that specifies the format of SYSIB 1.2.2.

**Alternate-CPU-Capability Offset:** When the format field has a value of one, bytes 2-3 of word 0 contain a 16-bit unsigned binary integer that specifies the offset in bytes of the alternate-CPU-capability field in the SYSIB.

**Secondary CPU Capability:** Word 7 contains a 32-bit unsigned binary integer that, when not zero, specifies a secondary capability that may be applied to certain types of CPUs in the configuration. There is no formal description of the algorithm used to generate this integer, except that it is the same as the algorithm used to generate the CPU capability. The integer is used as an indication of the capability of a CPU relative to the capability of other CPU models, and also relative to the capability of other CPU types within a model.

The capability value applies to each of the CPUs of one or more applicable CPU types in the configuration. That is, all CPUs in the configuration of an applicable type or types have the same capability. When the value is zero, all CPUs of any CPU type in the configuration have the same capability, as specified by the CPU capability.

The secondary CPU capability may or may not be the same value as the CPU-capability value.

The multiprocessing-CPU-capability-adjustment factors are also applicable to CPUs whose capability is specified by the secondary CPU capability.

**CPU Capability:** If bits 0-8 of word 8 are zero, the word contains a 32-bit unsigned binary integer ( $I$ ) in the range  $0 \leq I < 2^{23}$  that specifies the capability of one of the CPUs in the configuration. If bits 0-8 of word 8 are nonzero, the word contains a 32-bit binary floating point short-format number instead of a 32-bit unsigned binary integer.

Regardless of encoding, a lower value indicates a proportionally higher CPU capacity. Beyond that, there is no formal description of the algorithm used to generate this value. The value is used as an indica-

tion of the capability of the CPU relative to the capability of other CPU models.

The capability value applies to each of the non-secondary CPUs in the configuration. That is, all non-secondary CPUs in the configuration have the same capability.

**Total CPU Count:** Bytes 0 and 1 of word 9 contain a 16-bit unsigned binary integer that specifies the total number of CPUs in the configuration. This number includes all CPUs in the configured state, the standby state, or the reserved state.

**Configured CPU Count:** Bytes 2 and 3 of word 9 contain a 16-bit unsigned binary integer that specifies the number of CPUs that are in the configured state. A CPU is in the configured state when it is in the configuration and available to be used to execute programs.

**Standby CPU Count:** Bytes 0 and 1 of word 10 contain a 16-bit unsigned binary integer that specifies the number of CPUs that are in the standby state. A CPU is in the standby state when it is in the configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

**Reserved CPU Count:** Bytes 2 and 3 of word 10 contain a 16-bit unsigned binary integer that specifies the number of CPUs that are in the reserved state. A CPU is in the reserved state when it is in the configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place a reserved CPU in the standby or configured state by means of manual actions.)

**Multiprocessing CPU-Capability Adjustment Factors:** Beginning with bytes 0 and 1 of word 11, the SYSIB contains a series of contiguous two-byte fields, each containing a 16-bit unsigned binary integer used to form an adjustment factor (fraction) for the value contained in the CPU-capability field. Such a fraction is developed by using the value (V) of the first two-byte field according to one of the following methods:

- If V is in the range  $0 < V \leq 100$ , a denominator of 100 is indicated which produces a fraction of  $V/100$ .

- If V is in the range  $101 \leq V < 255$ , a denominator of 255 is indicated which produces a fraction of  $V/255$ .
- If V is in the range  $255 \leq V < 65,536$ , a denominator of 65,536 is indicated which produces a fraction of  $V/65,536$ .

Thus, the fraction represented by each two-byte field is then developed by dividing the contents of a two-byte field by the indicated denominator.

The number of adjustment-factor fields is one less than the number of CPUs specified in the total-CPU-count field. The adjustment-factor fields correspond to configurations with increasing numbers of CPUs in the configured state. The first adjustment-factor field corresponds to a configuration with two CPUs in the configured state. Each successive adjustment-factor field corresponds to a configuration with a number of CPUs in the configured state that is one more than that for the preceding field.

**Alternate CPU Capability:** When the format field has a value of one, if bits 0-8 of word N are zero, the word contains a 32-bit unsigned binary integer (I) in the range  $0 \leq I < 2^{23}$  that specifies the announced capability of one of the CPUs in the configuration. If bits 0-8 of word N are nonzero, the word contains a 32-bit binary floating point short-format number instead of a 32-bit unsigned binary integer.

Regardless of encoding, a lower value indicates a proportionally higher CPU capacity. Beyond that, there is no formal description of the algorithm used to generate this value. The value is used as an indication of the announced capability of the CPU relative to the announced capability of other CPU models.

The alternate-capability value applies to each of the CPUs in the configuration. That is, all CPUs in the configuration have the same alternate capability.

**Alternate Multiprocessing CPU-Capability Adjustment Factors:** Beginning with bytes 0 and 1 of word N+1, the SYSIB contains a series of contiguous two-byte fields, each containing a 16-bit unsigned binary integer used to form an adjustment factor (fraction) for the value contained in the alternate-CPU-capability field. Such a fraction is developed by using the value (V) of the first two-byte field according to one of the following methods:

- If V is in the range  $0 < V \leq 100$ , a denominator of 100 is indicated which produces a fraction of  $V/100$ .
- If V is in the range  $101 \leq V < 255$ , a denominator of 255 is indicated which produces a fraction of  $V/255$ .
- If V is in the range  $255 \leq V < 65,536$ , a denominator of 65,536 is indicated which produces a fraction of  $V/65,536$ .

Thus, the fraction represented by each two-byte field is then developed by dividing the contents of a two-byte field by the indicated denominator.

The number of alternate-adjustment-factor fields is one less than the number of CPUs specified in the total-CPU-count field. The alternate-adjustment-factor fields correspond to configurations with increasing numbers of CPUs in the configured state. The first alternate-adjustment-factor field corresponds to a configuration with two CPUs in the configured state. Each successive alternate-adjustment-factor field corresponds to a configuration with a number of CPUs in the configured state that is one more than that for the preceding field.

### SYSIB 2.2.1 (Logical-Partition CPU)

SYSIB 2.2.1 has the following format:

SYSIB 2.2.1	
0	Reserved
20	Sequence Code
24	Plant of Manufacture
25	LCPU ID
26	LCPU Address
1023	Reserved

**Reserved:** The contents of words 0-19 and 26-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

**Sequence Code:** Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The code is right justified with leading EBCDIC zeros if necessary.

**Plant of Manufacture:** Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

**Logical-CPU ID:** Bytes 0 and 1 of word 25 contain a 16-bit unsigned binary integer that can be used in conjunction with the logical-CPU address to distinguish the logical CPU from the other logical CPUs provided by the same LPAR hypervisor.

**Logical-CPU Address:** Bytes 2 and 3 of word 25 contain the logical-CPU address by which this logical CPU is identified within the level-2 configuration. The logical-CPU address is a 16-bit unsigned binary integer.

The logical-CPU-address field contains the same information as is stored by STORE CPU ADDRESS when the machine is operating in the LPAR mode.

**Programming Note:** Multiple logical CPUs in the same level-2 configuration have the same logical-CPU sequence code, and it is necessary to use other information, such as the logical-CPU address, to establish a unique logical-CPU identity. The sequence code returned for a basic-machine CPU and a logical-partition CPU are identical and have the same value as the sequence code returned for the basic-machine configuration.

### SYSIB 2.2.2 (Logical-Partition CPUs)

SYSIB 2.2.2 has the following format:

SYSIB 2.2.2			
0	Reserved		
8	LPAR Number	Reserved	LCPUC
9	Total LCPU Count	Configured LCPU Count	
10	Standby LCPU Count	Reserved LCPU Count	
11	Logical-Partition Name		
13	Logical-Partition CAF		
14	Model-Dependent Data		
16	Reserved		
18	Dedicated LCPU Count	Shared LCPU Count	
19	Reserved		
1023			
0	16	24	31

**Reserved:** The contents of words 0-7, byte 2 of word 8, words 16-17, and words 19-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

**Logical-Partition Number:** Bytes 0 and 1 of word 8 contain a 16-bit unsigned binary integer which is the number of the level-2 configuration. This number distinguishes the configuration from all other level-2 configurations provided by the same LPAR hypervisor.

**Logical-CPU Characteristics (LCPUC):** The contents of byte 3 of word 8 describe the characteristics of the logical CPUs that are provided for the level-2 configuration. The bits and their meanings are as follows:

#### Bit Meaning

- 0 Dedicated: When one, bit 0 indicates that one or more of the logical CPUs for this level-2 configuration are provided using level-1 CPUs that are dedicated to this level-2 configuration and are not

used to provide logical CPUs for any other level-2 configuration. The number of logical CPUs that are provided using dedicated level-1 CPUs is specified by the dedicated-LCPU-count value in bytes 0 and 1 of word 18.

When zero, bit 0 indicates that none of the logical CPUs for this level-2 configuration are provided using level-1 CPUs that are dedicated to this level-2 configuration.

- 1 Shared: When one, bit 1 indicates that one or more of the logical CPUs for this level-2 configuration are provided using level-1 CPUs that can be used to provide logical CPUs for other level-2 configurations. The number of logical CPUs that are provided using shared level-1 CPUs is specified by the shared-LCPU-count value in bytes 2 and 3 of word 18.

When zero, bit 1 indicates that none of the logical CPUs for this level-2 configuration are provided using shared level-1 CPUs.

- 2 Utilization Limit: When one, bit 2 indicates that the amount of use of the level-1 CPUs that are used to provide the logical CPUs for this level-2 configuration is limited.

When zero, bit 2 indicates that the amount of use of the level-1 CPUs that are used to provide the logical CPUs for this level-2 configuration is unlimited.

- 3-7 Reserved.

**Total Logical-CPU Count:** Bytes 0 and 1 of word 9 contain a 16-bit unsigned binary integer that specifies the total number of logical CPUs that are provided for this level-2 configuration. This number includes all of the logical CPUs that are in the configured state, the standby state, or the reserved state.

**Configured Logical-CPU Count:** Bytes 2 and 3 of word 9 contain a 16-bit unsigned binary integer that specifies the number of logical CPUs for this level-2 configuration that are in the configured state.

A logical CPU is in the configured state when it is in the level-2 configuration and is available to be used to execute programs.

**Standby Logical-CPU Count:** Bytes 0 and 1 of word 10 contain a 16-bit unsigned binary integer that specifies the number of logical CPUs for this level-2 configuration that are in the standby state.

A logical CPU is in the standby state when it is in the level-2 configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

**Reserved Logical-CPU Count:** Bytes 2 and 3 of word 10 contain a 16-bit unsigned binary integer that specifies the number of CPUs for this level-2 configuration that are in the reserved state.

A logical CPU is in the reserved state when it is in the level-2 configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place the reserved CPU in the standby or configured state through manual actions.)

**Logical-Partition Name:** Words 11-12 contain the 8-character EBCDIC name of this level-2 configuration. The name is left justified with trailing blanks if necessary.

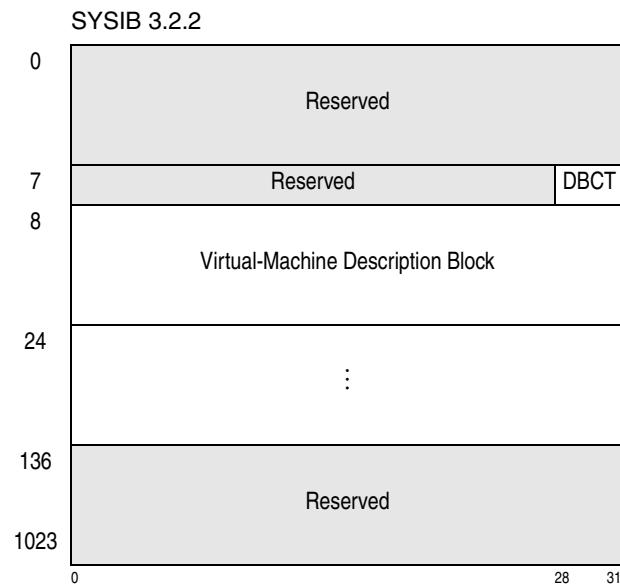

**Logical-Partition Capability Adjustment Factor (CAF):** Word 13 contains a 32-bit unsigned binary integer, called an adjustment factor, with a value of 1000 or less. The adjustment factor specifies the amount of the underlying level-1-configuration capability that is allowed to be used for this level-2 configuration by the LPAR hypervisor. The fraction of level-1-configuration capability is determined by dividing the CAF value by 1000.

**Dedicated Logical-CPU Count:** Bytes 0 and 1 of word 18 contain a 16-bit unsigned binary integer that specifies the number of configured-state logical CPUs for this level-2 configuration that are provided using dedicated level-1 CPUs. (See the description of bit 0 of the logical-CPU-characteristics field.)

**Shared Logical-CPU Count:** Bytes 2 and 3 of word 18 contain a 16-bit unsigned binary integer that specifies the number of configured-state logical CPUs for this level-2 configuration that are provided using shared level-1 CPUs. (See the description of bit 1 of the logical-CPU-characteristics field.)

### SYSIB 3.2.2 (Virtual-Machine CPUs)

SYSIB 3.2.2 has the following format:

**Reserved:** The contents of words 0-6, bits 0-27 of word 7, and words 136-1023 are reserved and are stored as zeros.

**Description-Block Count (DBCT):** Bits 28-31 of word 7 contain a four-bit unsigned binary integer that specifies the number (up to eight) of virtual-machine description blocks that are stored in the SYSIB beginning at word 8.

**Virtual-Machine Description Blocks:** Words 8-135 contain from one to eight 64-byte virtual-machine description blocks, depending on the number of nested level-3 configurations, if any, and their processing characteristics.

When a level-3 configuration is provided by a virtual-machine control program and the control program is being executed by a level-3 configuration provided by another virtual-machine control program, the level-3 configurations are said to be “nested.” Level-3 configurations can be nested in this way for several levels.

The collection of nested level-3 configurations that is in the path between a program being executed by a level-3 configuration and the basic machine is called a “level-3-configuration stack.” The level-3 configurations in a stack are consecutively numbered. The level-3 configuration provided by a virtual-machine control program being executed by either a level-2

configuration or a level-1 configuration is the lowest-numbered (0) level-3 configuration in the stack. The level-3 configuration that is executing the program containing this instruction is the highest numbered (N) level-3 configuration in the stack.

If more than one virtual-machine description block is stored in words 8-135 of the SYSIB, the blocks are stored according to the following rules:

- The collection of level-3 configurations described is a contiguous subset of the total collection of level-3 configurations in the level-3-configuration stack. The subset always includes the highest-numbered level-3 configuration in the stack. One or more level-3 configurations at the bottom of the stack may not be described because STORE SYSTEM INFORMATION is not implemented by the highest of those configurations or the limit of eight description blocks would be exceeded.
- The highest-numbered level-3 configuration in the level-3-configuration stack is always described by the first description block in the SYSIB. The lowest-numbered level-3 configuration in the stack, of those that are included in the subset that is described, is described by the last description block in the SYSIB.

The contents of the SYSIB subsequent to the virtual-machine description blocks and prior to word 136 are reserved and are stored as zeros.

The virtual-machine description block has the following format:

Virtual-Machine Description Block					
0	Reserved				
1	Total LCPU Count	Configured LCPU Count			
2	Standby LCPU Count	Reserved LCPU Count			
3	Virtual-Machine Name				
4					
5	Virtual-Machine CAF				
6	Control-Program Identifier				
10	Reserved				
15					

16

31

**Reserved:** The contents of words 0 and 10-15 are reserved and are stored as zeros.

**Total Logical-CPU Count:** Bytes 0 and 1 of word 1 contain a 16-bit unsigned binary integer that specifies the total number of logical CPUs that are provided for this level-3 configuration. This number includes all of the logical CPUs that are in the configured state, the standby state, and the reserved state.

**Configured Logical-CPU Count:** Bytes 2 and 3 of word 1 contain a 16-bit unsigned binary integer that specifies the number of logical CPUs for this level-3 configuration that are in the configured state.

A logical CPU is in the configured state when it is in the level-3 configuration and is available to be used to execute programs.

**Standby Logical-CPU Count:** Bytes 0 and 1 of word 2 contain a 16-bit unsigned binary integer that specifies the number of logical CPUs for this level-3 configuration that are in the standby state.

A logical CPU is in the standby state when it is in the level-3 configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

**Reserved Logical-CPU Count:** Bytes 2 and 3 of word 2 contain a 16-bit unsigned binary integer that specifies the number of CPUs for this level-3 configuration that are in the reserved state.

A logical CPU is in the reserved state when it is in the level-3 configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place the logical CPU in the standby or configured state through manual actions.)

**Virtual-Machine Name:** Words 3-4 contain the eight-character EBCDIC name of this level-3 configuration. The name is left justified with trailing blanks if necessary.

**Virtual-Machine Capability Adjustment Factor (CAF):** Word 5 contains a 32-bit unsigned binary integer, called an adjustment factor, with a value of 1000 or less. The adjustment factor specifies the amount of the underlying level-1-, level-2-, or level-3-configuration capability that is allowed to be used for this level-3 configuration by the virtual-machine control program. The fraction of the underly-

ing capability is determined by dividing the CAF value by 1000.

**Control-Program Identifier:** Words 6-9 contain the 16-character EBCDIC identifier of the virtual-machine control program that provides this level-3 configuration. This identifier may include qualifiers such as version number and release level. The identifier is left justified with trailing blanks if necessary.

### SYSIB 15.1.2 (Configuration Topology)

SYSIB 15.1.2 has the following format:

SYSIB 15.1.2

Reserved				Length
0	Mag6	Mag5	Mag4	Mag3
1	Mag2	Mag1	Reserved	MNest
2	Reserved			
3	Topology List			
4				
:				
N-1				
N	Reserved			
1023				

0            8            16            24            31

**Reserved:** The contents of bytes 0-1 of word 0, byte 2 of word 2, and word 3 are reserved and are stored as zeros. The contents of words N-1023 are reserved and may be stored as zeros or may remain unchanged.

**Length:** Bytes 2-3 of word 0 contain a 16-bit unsigned binary integer whose value is the count of bytes of the entire SYSIB 15.1.2. The length of just the topology list is determined by subtracting 16 from the length value in bytes 2-3 of word 0. N in Figure 10-61 is determined by evaluating the formula  $N=Length/4$ .

**Mag1-6:** Word 1 and bytes 0-1 of word 2 constitute six one-byte fields where the content of each byte indicates the maximum number of container-type topology-list entries (TLE) or CPU-type TLEs at the corresponding nesting level. CPU-type TLEs are always found only at the Mag1 level. Additionally, the Mag1 value also specifies the maximum number of CPUs that may be represented by a container-type TLE of the Mag2 level. When the value of the nesting level is greater than one, containing nesting levels above the Mag1 level are occupied only by container-

type TLEs. A dynamic change to the topology may alter the number of TLEs and the number of CPUs at the Mag1 level, but the limits represented by the values of the Mag1-6 fields do not change within a model family of machines.

The topology is a structured list of entries where an entry defines one or more CPUs or else is involved with the nesting structure. The following illustrates the meaning of the magnitude fields:

- When all CPUs of the machine are peers and no containment organization exists, other than the entirety of the central-processing complex itself, the value of the nesting level is 1, Mag1 is the only non-zero magnitude field, and the number of CPU-type TLEs stored does not exceed the Mag1 value.
- When all CPUs of the machine are subdivided into peer groups such that one level of containment exists, the value of the nesting level is 2, Mag1 and Mag2 are the only non-zero magnitude fields, the number of container-type TLEs stored does not exceed the Mag2 value, and the number of CPU-type TLEs stored within each container does not exceed the Mag1 value.
- The Mag3-6 bytes similarly become used (proceeding in a right-to-left direction) when the value of the nesting level falls in the range 3-6.

**MNest:** Byte 3 of word 2 specifies the nesting level of the topology to which the configuration may be extended while continuing to allow the guest program to survive. The maximum MNest value is six; the minimum is one. If MNest is one, there is no actual TLE nesting structure, Mag1 is the only non-zero field in the Mag1-6 range, and only CPU-type TLEs are represented in the topology list. The MNest value indicates the number of non-zero magnitude values beginning with the magnitude field at byte 1 of word 2 (Mag1), proceeding left when MNest is greater than one, and with the remaining magnitude fields stored as zeros.

The value of MNest is the maximum possible nesting. No dynamic configuration change exceeds this limit.

**Topology List:** Words of Figure 10-61 in the range 4 through N-1 specify a list of one or more topology-list entries (TLE). Each TLE is an eight-byte or sixteen-byte field; thus N is an even number of words,

and a corollary is that a TLE always starts on a doubleword boundary.

**Topology-List Entries:** The first TLE in the topology list begins at a nesting level equal to MNest-1. The entire topology list represents the configuration of the issuer of the STSI instruction specifying SYSIB 15.1.2; no outermost container TLE entry is used as it would be redundant with the entire list, and the entire configuration. Therefore, the highest nesting level may have more than a single peer container.

Figure 10-61 illustrates the types of TLEs:

Word	TLE type - Container:		
0	NL>0	Reserved	
1	0 0 0 0 0 0 0	Reserved	Container ID
	0 8	24	31
Word	TLE type - CPU:		
0	NL=0	Reserved	
1	0 0 0 0   DPP	CPU Type	CPU Address Origin
2	CPU Mask		
3	0 5 6 8	16	31

Figure 10-61. Topology-List Entries

**Nesting Level (NL):** Byte 0 of word 0 specifies the TLE nesting level.

#### NL Meaning

- 00 The TLE is a CPU-type TLE.
- 01-05 The TLE is a container-type TLE. The first container-type TLE stored in a topology list or a parent container has a container-ID in the range 1-255. If sibling containers exist within the same parent, they proceed in an ascending order of container IDs, that may or may not be consecutive, to a maximum value of 255.
- 06-FF Reserved

Sibling TLEs have the same value of nesting level which is equivalent to either the value of the nesting level minus one of the immediate parent TLE, or the value of MNest minus one, because the immediate parent is the topology list rather than a TLE.

**Reserved, 0:** For a container-type TLE, bytes 1-3 of word 0 and bytes 0-2 of word 1 are reserved and stored as zeros. For a CPU-type TLE, bytes 1-3 of word 0 and bits 0-4 of word 1 are reserved and stored as zeros.

**Container ID:** Byte 3 of word 1 of a container-type TLE specifies an 8-bit unsigned non-zero binary integer whose value is the identifier of the container. The container ID for a TLE is unique within the same parent container.

**Dedicated (D):** Bit 5 of word 1 of a CPU-type TLE, when one, indicates that the one or more CPUs represented by the TLE are dedicated. When D is zero, the one or more CPUs of the TLE are not dedicated.

**Polarization (PP):** Bits 6-7 of word 1 of a CPU-type TLE specify the polarization value and, when polarization is vertical, the degree of vertical polarization also called entitlement (high, medium, low) of the corresponding CPU(s) represented by the TLE. The following values are used:

PP	Meaning
0	The one or more CPUs represented by the TLE are horizontally polarized.
1	The one or more CPUs represented by the TLE are vertically polarized. Entitlement is low.
2	The one or more CPUs represented by the TLE are vertically polarized. Entitlement is medium.
3	The one or more CPUs represented by the TLE are vertically polarized. Entitlement is high.

Polarization is only significant in a logical and virtual multiprocessing configuration that uses shared host processors and addresses how the resource assigned to a configuration is applied across the CPUs of the configuration. When horizontal polarization is in effect, each CPU of a configuration is guaranteed approximately the same amount of resource. When vertical polarization is in effect, CPUs of a configuration are classified into three levels of resource entitlement: high, medium, and low.

Both subsystem reset and successful execution of the SIGP set-architecture order specifying ESA/390 mode place a configuration and all of its CPUs into horizontal polarization. The CPUs immediately affected are those that are in the configured state. When a CPU in the standby state is configured, it acquires the current polarization of the configuration and causes a topology change of that configuration to be recognized.

A dedicated CPU is either horizontally or vertically polarized. When a dedicated CPU is vertically polarized, entitlement is always high. Thus, when D is one, PP is either 00 binary or 11 binary.

**CPU Type:** Byte 1 of word 1 of a CPU-type TLE specifies an 8-bit unsigned binary integer whose value is the CPU type of the one or more CPUs represented by the TLE. The CPU-type value specifies either a primary-CPU type or any one of the possible secondary-CPU types.

**CPU-Address Origin:** Bytes 2-3 of word 1 of a CPU-type TLE specify a 16-bit unsigned binary integer whose value is the CPU address of the first CPU in the range of CPUs represented by the CPU mask, and whose presence is represented by the value of bit position 0 in the CPU mask. A CPU-address origin is evenly divisible by 64. The value of a CPU-address origin is the same as that stored by the STORE CPU ADDRESS (STAP) instruction when executed on the CPU represented by bit position 0 in the CPU mask.

**CPU Mask:** Words 2-3 of a CPU-type TLE specify a 64-bit mask where each bit position represents a CPU. The value of the CPU-address origin field plus a bit position in the CPU mask equals the CPU address for the corresponding CPU.

When a CPU mask bit is zero, the corresponding CPU is not represented by the TLE. The CPU is either not in the configuration or else must be represented by another CPU-type TLE.

When a CPU mask bit is one, the corresponding CPU has the modifier-attribute values specified by the TLE, is in the topology of the configuration, and is not present in any other TLE of the topology.

Thus, for example, if the CPU-address origin is a value of 64, and bit position 15 of the CPU mask is one, CPU 79 is in the configuration and has the CPU type, polarization, entitlement, and dedication as specified by the TLE.

**TLE Ordering:** The modifier attributes that apply to a CPU-type TLE are CPU type, polarization, entitlement, and dedication. Polarization and entitlement (for vertical polarization) are taken as a single attribute, albeit with four possible values (horizontal, vertical-high, vertical-medium, and vertical-low).

A single CPU TLE is sufficient to represent as many as 64 CPUs that all have the same modifier-attribute values.

When more than 64 CPUs exist, or the entire range of CPU addresses are not covered by a single CPU-address origin, and the modifier attributes are con-

stant, a separate sibling CPU TLE is stored for each CPU-address origin, as necessary, in ascending order of CPU-address origin. Each such TLE stored has at least one CPU represented. The collection of one or more such CPU TLEs is called a CPU-TLE set.

When multiple CPU types exist, a separate CPU-TLE set is stored for each, in ascending order of CPU type.

When multiple polarization-and-entitlement values exist, a separate CPU-TLE set is stored for each, in descending order of polarization value and degree (vertical high, medium, low, then horizontal). When present, all polarization CPU-TLE sets of a given CPU type are stored before the next CPU-TLE set of the next CPU type.

When both dedicated and not-dedicated CPUs exist, a separate CPU-TLE set is stored for each, dedicated appearing before not-dedicated.

All TLEs are ordered assuming a depth-first traversal where the sort order from major to minor is as follows:

1. CPU type
  - a. Lowest CPU-type value
  - b. Highest CPU-type value
2. Polarization-Entitlement
  - a. Vertical high
  - b. Vertical medium
  - c. Vertical low
  - d. Horizontal
3. Dedication (when applicable)
  - a. Dedicated
  - b. Not dedicated

The ordering by CPU-address origin and modifier attributes of sibling CPU TLEs within a parent container is done according to the following list, which proceeds from highest to lowest.

1. CPU-TLE set of lowest CPU-type value, vertical high, dedicated

2. CPU-TLE set of lowest CPU-type value, vertical high, not-dedicated
3. CPU-TLE set of lowest CPU-type value, vertical medium, not-dedicated
4. CPU-TLE set of lowest CPU-type value, vertical low, not-dedicated
5. CPU-TLE set of lowest CPU-type value, horizontal, dedicated
6. CPU-TLE set of lowest CPU-type value, horizontal, not-dedicated
7. CPU-TLE set of highest CPU-type value, vertical high, dedicated
8. CPU-TLE set of highest CPU-type value, vertical high, not-dedicated
9. CPU-TLE set of highest CPU-type value, vertical medium, not-dedicated
10. CPU-TLE set of highest CPU-type value, vertical low, not-dedicated
11. CPU-TLE set of highest CPU-type value, horizontal, dedicated
12. CPU-TLE set of highest CPU-type value, horizontal, not-dedicated

**Other TLE Rules :**

1. A container-type TLE is located at nesting levels in the range 1-5.
2. A CPU-type TLE is located at nesting level 0.
3. The number of sibling container-type TLEs in a topology list or a given parent container does not exceed the value of the magnitude byte (Mag2-6) of the nesting level corresponding to the siblings.
4. The number of CPUs represented by the one or more CPU-type TLEs of the parent container does not exceed the value of the Mag1 magnitude byte.
5. The content of a TLE is defined as follows:
  - If a TLE is a container-type TLE, the content is a list that immediately follows the parent TLE, comprised of one or more child TLEs, and each child TLE has a nesting level of one less than the nesting level of the parent TLE or topology-list end.

- If a TLE is a CPU-type TLE, the content is one or more CPUs, as identified by the other fields of a CPU TLE.

6. When the first TLE at a nesting level is a CPU entry, the maximum nesting level 0 has been reached.

## CPU Topology Overview

With the advent of the IBM System z9 (2094 z9 EC) and subsequent models, and even previously, machine organization into nodal structures has resulted in a non-uniform memory access (NUMA) behavior, sometimes also called “lumpiness”. The purpose of the SYSIB 15.1.2 and the PERFORM TOPOLOGY FUNCTION (PTF) instruction is to provide additional machine topology awareness to the program so that certain optimizations can be performed to improve cache-hit ratios and thereby improve overall performance.

The amount of host-CPU resource assigned to a multiprocessing (MP) guest configuration has generally been spread evenly across the number of configured guest CPUs. Such an even spread implies that no particular guest CPU or CPUs are entitled to any extra host-CPU provisioning than any other, arbitrarily-determined guest CPUs. This condition of the guest configuration, affecting all CPUs of the configuration, is called *horizontal polarization*.

Under horizontal polarization, assignment of a host CPU to a guest CPU is approximately the same amount of provisioning for each guest CPU. When the provisioning is not dedicated, the same host CPUs provisioning the guest CPUs also may be used to provision guest CPUs of another guest, or even other guest CPUs of the same guest configuration. When the other guest configuration is a different logical partition, a host CPU, when active in each partition, typically must access main storage more because the cache-hit ratio is reduced by having to share the caches across multiple relocation zones. If host-CPU provisioning can alter the balance such that some host CPUs are mostly, or even exclusively, assigned to a given guest configuration, and that becomes the normal behavior, then cache-hit ratios improve, as does performance. Such an uneven spread implies that one or more guest CPUs are entitled to extra host-CPU provisioning versus other, arbitrarily-determined guest CPUs that are entitled to less host-CPU provisioning. This condition of the guest configuration, affecting all CPUs of the configuration, is called *vertical polarization*.

The architecture categorizes vertical polarization into three levels of entitlement of provisioning, high, medium, and low:

- High entitlement guarantees approximately 100% of a host CPU being assigned to a logical/virtual CPU, and the affinity is maintained as a strong correspondence between the two. With respect to provisioning of a logical partition, when vertical polarization is in effect, the entitlement of a dedicated CPU is defined to be high.
- Medium entitlement guarantees an unspecified amount of host CPU resource (one or more host CPUs) being assigned to a logical/virtual CPU, and any remaining capacity of the host CPU is considered to be slack that may be assigned elsewhere. The best case for the available slack would be to assign it as local slack if that is possible. A less-beneficial result occurs if that available slack is assigned as remote slack. (See “CPU Slack” on page 10-138 for descriptions of the two slack terms.) It is also the case that the resource percentage assigned to a logical CPU of medium entitlement is a much softer approximation as compared to the 100% approximation of a high-entitlement setting.
- Low entitlement guarantees approximately 0% of a host CPU being assigned to a logical/virtual CPU. However, if slack is available, such a logical/virtual CPU may still receive some CPU resource.

A model of nested containers using polarization is intended to provide a level of intelligence about the machine's nodal structure as it applies to the requesting configuration, so that, generally, clusters of host CPUs can be assigned to clusters of guest CPUs, thereby improving as much as possible the sharing of storage and the minimizing of different configurations essentially colliding on the same host CPUs.

Polarization and entitlement indicate the relationship of physical CPUs to logical CPUs or logical CPUs to virtual CPUs in a guest configuration, and how the capacity assigned to the guest configuration is apportioned across the CPUs that comprise the configuration. Historically, a guest configuration has been horizontally polarized. For however many guest CPUs were defined to the configuration, the host-CPU resource assigned was spread evenly across all of the guest CPUs in an equitable, non-entitled manner.

It can be said that the weight of a single logical CPU in a logical partition when horizontal polarization is in effect is approximately equal to the total configuration weight divided by the number of CPUs. However, with the introduction of the 2097 and family models, it becomes imperative to be able to spread the host-CPU resource in a different manner, which is called vertical polarization of a configuration, and then the degree of provisioning of guest CPUs with host CPUs being indicated as high, medium, or low entitlement. High entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is entirely backed by the same host CPU. Medium entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is partially backed by a host CPU. Low entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is not guaranteed any host-CPU resource, other than what might become available due to slack resource becoming available.

## CPU Slack

Regarding slack CPU resource, there are two kinds:

- Local slack becomes available when a logical/virtual CPU of a configuration is not using all the resource to which it is entitled and such slack is then used within the configuration of that CPU. Local slack is preferred over remote slack as better hit ratios on caches are expected when the slack is used within the configuration.
- Remote slack becomes available when a logical/virtual CPU of a configuration is not using all the resource to which it is entitled and such slack is then used outside the configuration of that CPU. Remote slack is expected to exhibit lower hit ratios on caches, but it is still better than not running a logical/virtual CPU at all.

The goal is to maximize the CPU cache hit ratios.

For a logical partition, the amount of physical-CPU resource is determined by the overall system weightings that determine the CPU resource assigned to each logical partition. For example, in a logical 3-way MP that is assigned physical-CPU resource equivalent to a single CPU, and is horizontally polarized, each logical CPU would be dispatched independently and thus receive approximately 33% physical-CPU resource. If the same configuration were to be vertically polarized, only a single logical CPU would be run and would receive approximately 100% of the assigned physical-CPU resource (high entitlement)

while the remaining two logical CPUs would not normally be dispatched (low entitlement). Such resource assignment is normally an approximation. Even a low-entitlement CPU may receive some amount of resource if only to help ensure that a program does not get stuck on such a CPU.

By providing a means for a control program to indicate that it understands polarization, and to receive an indication for each CPU of its polarization and, if vertical polarization, the degree of entitlement, the control program can make more-intelligent use of data structures that are generally thought to be local to a CPU vs. available to all CPUs of a configuration. Also, such a control program can avoid directing work to any low-entitlement CPU.

The actual physical-CPU resource assigned might not constitute an integral number of CPUs, so there is also the possibility of one or more CPUs in an MP vertically-polarized configuration being entitled but not to a high degree, thereby resulting in such CPUs having either medium or low vertical entitlement.

It is possible for any remaining low-entitlement CPUs to receive some amount of host-CPU resource. For example, this may occur when such a CPU is targeted, such as via a SIGP order and slack host-CPU resource is available. Otherwise, such a logical/virtual CPU might remain in an undispatched state, even if it is otherwise capable of being dispatched.

A 2-bit polarization field is defined for the CPU-type topology-list entry (TLE) of the STORE SYSTEM INFORMATION (STSI) instruction. The degree of vertical-polarization entitlement for each CPU is indicated as high, medium, or low. The assignment is not a precise percentage but rather is somewhat fuzzy and heuristic.

In addition to vertical polarization as a means of reassigning weighting to guest CPUs, another concept exists, which is the creation and management of slack capacity (also called “whitespace”). Slack capacity is created under the following circumstances:

- A high-vertical CPU contributes to slack when its average utilization (AU) falls below 100 percent (100-AU).
- A medium-vertical CPU that has an assigned provisioning of M percent of a host CPU contrib-

utes to slack when its average utilization (AU) falls below M percent ( $M-AU > 0$ ).

- A low-vertical CPU does not contribute to slack.
- A high-vertical CPU is not a consumer of slack.
- A medium-vertical CPU may or may not be a consumer of slack.
- A low-vertical CPU is only a consumer of slack.

Depending upon its utilization and pattern of being dispatched, a horizontally-polarized CPU can be either a contributor to slack or a consumer of it.

**Programming Note:** A possible examination process of a topology list is described. Before an examination of a topology list is begun, the current-TLE pointer is initialized to reference the first or top TLE in the topology list, the prior-TLE pointer is initialized to null, and then TLEs are examined in a top-to-bottom order.

As a topology-list examination proceeds, the current-TLE pointer is advanced by incrementing the current-TLE pointer by the size of the current TLE to which it points. A container-type TLE is advanced by adding eight to the current-TLE pointer. A CPU-type TLE is advanced by adding sixteen to the current-TLE pointer. The process of advancing the current-TLE pointer includes saving its value as the prior-TLE pointer just before it is incremented. TLE examination is not performed if the topology list has no TLEs.

The examination process is outlined in the following steps:

1. If the current-TLE nesting level is zero, and the prior-TLE nesting level is null or one, the current TLE represents the first CPU-type TLE of a group of one or more CPU-type TLEs. The program should perform whatever action is appropriate for when a new group of one or more CPUs is first observed. Go to step 5.
2. If the current-TLE nesting level is zero, and the prior-TLE nesting level is zero, the current TLE represents a subsequent CPU-type TLE of a group of CPU-type TLEs that represent siblings of the CPUs previously observed in steps 1 or 2. The program should perform whatever action is appropriate for when the size of an existing sibling group of one or more CPUs is increased. Go to step 5.

3. If the current-TLE nesting level is not zero, and the prior-TLE nesting level is zero, the prior TLE represents a last or only CPU-type TLE of a group of one or more CPU-type TLEs. The program should perform whatever action is appropriate for when an existing group of one or more CPUs is completed. Go to step 5.

4. Go to step 5.

By elimination, this would be the case where the current-TLE nesting level is not zero, and the prior-TLE nesting level is not zero. If the current-TLE nesting level is less than the prior-TLE nesting level, the direction of topology-list traversal is toward a CPU-type TLE. If the current-TLE nesting level is greater than the prior-TLE nesting level, the direction of topology-list traversal is away from a CPU-type TLE. Container-type TLEs are being traversed leading to either (1) another group of CPU-type TLEs that are a separate group in the overall topology, or (2) the end of the topology list. In either case, no particular processing is required beyond advancing to the next TLE.

5. Advance to the next TLE position based upon the type of the current TLE. If the advanced current-TLE pointer is equivalent to the end of the topology list:

- a. No more TLEs of any type exist.
- b. If the prior-TLE nesting level is zero, the program should perform whatever action is appropriate for when an existing group of one or more CPUs is completed.
- c. The examination is complete.

Otherwise go to step 1.

### **Special Conditions**

The condition code is set to 3 if the function code in bit positions 32-35 of general register 0 is greater than the current-level number.

Bits 36-55 of general register 0 and 32-47 of general register 1 must be zero; otherwise, a specification exception is recognized.

When the function code is valid and nonzero, the following special conditions apply in an unpredictable order:

- The second operand must be designated on a 4K-byte boundary; otherwise, a specification exception is recognized.
- If the function-code, selector-1, and selector-2 combination is invalid, or if it is valid but the requested information is not available, the condition code is set to 3.

The priority of the recognition of exceptions and condition codes is shown in Figure 10-62.

### **Resulting Condition Code:**

- 0 Requested configuration-level number placed in general register 0 or requested SYSIB information stored
- 1 --
- 2 --
- 3 Requested SYSIB information not available

### **Program Exceptions:**

- Access (store, operand 2, only if function code nonzero)
- Privileged operation
- Specification

**Programming Note:** The storage-operand references for STORE SYSTEM INFORMATION may be multiple-access references. (See “Storage-Operand Consistency” on page 5-95.)

- |       |   |  |  |  |  |
|-------|---|--|--|--|--|
| 1.-6. | Exceptions with the same priority as the priority of program-interruption conditions for the general case.                    |  |  |  |  |
| 7.A   | Access exceptions for second instruction halfword.  |  |  |  |  |
| 7.B   | Privileged-operation exception for privileged instruction.  |  |  |  |  |
| 8.    | Condition code 3 due to function code greater than current-level number.  |  |  |  |  |
| 9.    | Specification exception due to bits 36-55 of general register 0 or bits 32-47 of general register 1 not zero.                 |  |  |  |  |
| 10.   | Condition code 0 due to function code 0.  |  |  |  |  |
| 11.A  | Specification exception due to second-operand address not designating a 4K-byte boundary.                                     |  |  |  |  |
| 11.B  | Condition code 3 due to invalid function-code, selector-1, and selector-2 combination or requested information not available. |  |  |  |  |
| 12.   | Access exceptions (store) for system-information block.   |  |  |  |  |
| 13.   | Condition code 0 due to information stored in system-information block.   |  |  |  |  |

Figure 10-62. Priority of Execution: STORE SYSTEM INFORMATION

## STORE THEN AND SYSTEM MASK

STNSM	D <sub>1</sub> (B <sub>1</sub> ),I <sub>2</sub>	[SI]		
'AC'	I <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	
0	8	16	20	31

Bits 0-7 of the current PSW are stored at the first-operand location. Then the contents of bit positions 0-7 of the current PSW are replaced by the logical AND of their original contents and the second operand.

### Special Conditions

The operation is suppressed on addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (store, operand 1)
- Privileged operation

**Programming Note:** STORE THEN AND SYSTEM MASK permits the program to set selected bits in the system mask to zeros while retaining the original contents for later restoration. For example, it may be necessary that a program, which has no record of the present status, disable program-event recording for a few instructions.

### Program Exceptions:

## STORE THEN OR SYSTEM MASK

STOSM	D <sub>1</sub> (B <sub>1</sub> ),I <sub>2</sub>	[SI]		
'AD'	I <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	
0	8	16	20	31

Bits 0-7 of the current PSW are stored at the first-operand location. Then the contents of bit positions 0-7 of the current PSW are replaced by the logical OR of their original contents and the second operand.

### Special Conditions

The value to be loaded into the PSW is not checked for validity before loading. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, if the contents of bit positions 0 and 2-4 of the PSW are not all zeros. In this case, the instruction is completed, and the instruction-length code is set to 2. The specification exception, which is listed as a program exception for this instruction, is described in "Early Exception Recognition" on page 6-8. It may be considered as occurring early in the process of preparing to execute the following instruction.

The operation is suppressed on addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

- Access (store, operand 1)

- Privileged operation
- Specification

**Programming Note:** STORE THEN OR SYSTEM MASK permits the program to set selected bits in the system mask to ones while retaining the original contents for later restoration. For example, the program may enable the CPU for I/O interruptions without having available the current status of the external-mask bit.

## STORE USING REAL ADDRESS

STURA	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B246'	R <sub>1</sub> R <sub>2</sub>	0 16 24 28 31

STURG	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B925'	R <sub>1</sub> R <sub>2</sub>	0 16 24 28 31

For STORE USING REAL ADDRESS (STURA), bits 32-63 of general register R<sub>1</sub> are stored in the word at the real-storage location addressed by the contents of general register R<sub>2</sub>. For STORE USING REAL ADDRESS (STURG), bits 0-63 of general register R<sub>1</sub> are stored in the doubleword at that real-storage location.

In the 24-bit addressing mode, bits 40-63 of general register R<sub>2</sub> designate the real-storage location, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, bits 33-63 of general register R<sub>2</sub> designate the real-storage location, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, bits 0-63 of general register R<sub>2</sub> designate the real-storage location.

Because it is a real address, the address designating the storage word or doubleword is not subject to dynamic address translation.

### Special Conditions

The contents of general register R<sub>2</sub> must designate a location on a word boundary for STURA or on a doubleword boundary for STURG; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Addressing (address specified by general register R<sub>2</sub>)
- Privileged operation
- Protection (store, operand 2, key-controlled protection and low-address protection)
- Specification

## TEST ACCESS

TAR	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
'B24C'	R <sub>1</sub> R <sub>2</sub>	0 16 24 28 31

The access-list-entry token (ALET) in access register R<sub>1</sub> is tested for exceptions recognized during access-register translation (ART). The extended authorization index (EAX) used is bits 32-47 of general register R<sub>2</sub>. The ALET is also tested for whether it designates the dispatchable-unit access list or the primary-space access list and for whether it is 00000000 or 00000001 hex.

When R<sub>1</sub> is 0, the actual contents of access register 0 are used in ART, instead of the 00000000 hex that is usually used.

Bits 0-31 and 48-63 of general register R<sub>2</sub> are ignored.

The operation does not depend on the translation mode — bits 5, 16, and 17 of the PSW are ignored.

When the ALET specified by means of the R<sub>1</sub> field is other than 00000000 or 00000001 hex, the ART process is applied to the ALET. The EAX specified by means of the R<sub>2</sub> field is called the effective EAX, and it is the EAX which is used by ART. When a condition exists that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

Exception Name	Cause
ALET specification	ALET bits 0-6 not all zeros
ALEN translation	Access-list entry (ALE) outside list or invalid (bit 0 is one)
ALE sequence	ALE sequence number (ALESN) in ALET not equal to ALESN in ALE

Exception Name	Cause
ASTE validity	ASN-second-table entry (ASTE) invalid (bit 0 is one)
ASTE sequence	ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE
Extended authority	ALE private bit not zero, ALE authorization index (ALEAX) not equal to effective EAX, and secondary bit selected by effective EAX either outside authority table or zero

When ART is completed without one of the above conditions being present, the instruction is completed by setting condition code 1 or 2, depending on whether the effective access list is the dispatchable-unit access list or the primary-space access list, respectively. The effective access list is the dispatchable-unit access list if bit 7 of the ALET is zero, or it is the primary-space access list if bit 7 is one. ART, including the obtaining of the effective access-list designation, is described in “Access-Register-Translation Process” on page 5-55.

When the ALET is 00000000 hex, the instruction is completed by setting condition code 0. When the ALET is 00000001 hex, the instruction is completed by setting condition code 3.

### Special Conditions

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration.

The operation is suppressed on all addressing exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-63 on page 10-144.

### Resulting Condition Code:

- 0 Access-list-entry token (ALET) is 00000000 hex
- 1 ALET designates the dispatchable-unit access list and does not cause exceptions in access-register translation (ART)
- 2 ALET designates the primary-space access list and does not cause exceptions in ART

- 3 ALET is 00000001 hex or causes exceptions in ART

### Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, or authority-table entry)

### Programming Notes:

1. TEST ACCESS permits a called program to check whether an ALET passed from the calling program is authorized for use by means of the calling program’s EAX. The calling program’s EAX can be obtained from the last linkage-stack state entry by means of EXTRACT STACKED STATE. The called program can thus avoid performing an operation for the calling program, through the use of the called program’s EAX, which the calling program is not authorized to perform by means of its own EAX.
2. When an ALET equal to 00000000 hex is passed during a program linkage performed by PROGRAM CALL with space switching (PC-ss), and the ALET conceptually designates the calling program’s primary address space and the called program’s secondary address space, the ALET must be changed to 00000001 hex before it is used by the called program. Condition code 0 of TEST ACCESS indicates a 00000000 hex ALET so that the ALET can be changed to 00000001 hex by the called program.
3. PROGRAM CALL to current primary (PC-cp) sets the secondary address space equal to the primary address space. PC-ss sets the secondary address space equal to the calling program’s primary address space, except that stacking PC-ss sets it equal to the called program’s primary address space when the secondary-ASN control in the entry-table entry used is one. In all these cases, a passed 00000001 hex ALET that conceptually designates the calling program’s secondary address space is not usable by the called program, even after any transformation (unless the operation was PC-cp and the calling program’s PASN and SASN are equal). This is why TEST ACCESS sets condition code 3 when the tested ALET is 00000001 hex.
4. After a PC-ss, a passed ALET that conceptually designates an entry in the primary-space access list of the calling program is not usable by the

called program. This is why TEST ACCESS sets condition code 2, instead of condition code 1, when the tested ALET designates the primary-space access list.

5. The control program may manage the ASN-second-table entry in a way that causes a correctable ASTE-validity or ASTE-sequence exception situation to exist; that is, a situation which, if it were to cause a program interruption during access-register translation, would be corrected by the control program so that access-register

translation could be completed successfully. In this case, the program should not use TEST ACCESS directly but should instead use a control-program service that uses TEST ACCESS and that corrects the situation, if possible, when condition code 3 is set. MVS/ESA provides the TESTART macro instruction for use instead of the direct use of TEST ACCESS.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.	Access exceptions for second instruction halfword.
8.	Condition code 0 due to access-list-entry-token (ALET) being 00000000 hex.
9.	Condition code 3 due to ALET being 00000001 hex or ALET bits 0-6 not being all zeros.
10.	Addressing exception for access to effective access-list designation.
11.	Condition code 3 due to access-list entry (ALE) being outside the list.
12.	Addressing exception for access to ALE.
13.	Condition code 3 due to ALE being invalid (bit 0 is 1) or access-list-entry sequence number (ALESN) in the ALET not being equal to the ALESN in the ALE.
14.	Addressing exception for access to ASN-second-table entry (ASTE).
15.	Condition code 3 due to ASTE being invalid (bit 0 is one) or ASTE sequence number (ASTESN) in the ALE not being equal to the ASTESN in the ASTE.
16.	Condition code 3 due to authority-table entry being outside table.
17.	Addressing exception for access to authority-table entry.
18.	Condition code 3 due to ALE private bit not being zero, ALE authorization index (ALEAX) not being equal to effective extended authorization index (EAX), and secondary bit selected by effective EAX being zero.
19.	Condition code 1 if ALET bit 7 is zero; otherwise, condition code 2.

Figure 10-63. Priority of Execution: TEST ACCESS

## TEST BLOCK

TB	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
0	'B22C'	R <sub>1</sub> R <sub>2</sub>

The storage locations and storage key of a 4K-byte block are tested for usability, and the result of the test is indicated in the condition code. The test for usability is based on the susceptibility of the block to the occurrence of invalid checking-block code.

The block tested is addressed by the contents of general register R<sub>2</sub>. The contents of general register R<sub>1</sub> are ignored.

A complete testing operation is necessarily performed only when the initial contents of bit positions 32-63 of general register 0 are zero in the 24-bit or 31-bit addressing mode, or the initial contents of bit positions 0-63 of that register are zero in the 64-bit addressing mode. In the 24-bit or 31-bit addressing mode, the contents of bit positions 32-63 of general register 0 are set to zero at the completion of the operation, and bits 0-31 of the register always are

ignored and remain unchanged. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register are set to zero at the completion of the operation.

If the block is found to be usable, the 4K bytes of the block are cleared to zeros, the contents of the storage key are unpredictable, and condition code 0 is set. If the block is found to be unusable, the data and the storage key are set, as far as is possible by the model, to a value such that subsequent fetches to the area do not cause a machine-check condition, and condition code 1 is set.

In the 24-bit addressing mode, bits 40-51 of general register R<sub>2</sub> designate a 4K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of the register designate the block, and bits 0-32 and 52-63 are ignored. In the 64-bit addressing mode, bits 0-51 of the register designate the block, and bits 52-63 are ignored.

The address of the block is a real address, and the accesses to the block designated by the second-operand address are not subject to key-controlled, access-list-controlled, and DAT protection. Low-address protection does apply. The operation is terminated on addressing and protection exceptions. If termination occurs, the condition code and the contents of bit positions 32-63 of general register 0 are unpredictable in the 24-bit or 31-bit addressing mode, or the condition code and bits 0-63 of the register are unpredictable in the 64-bit addressing mode. The contents of the storage block and its associated storage key are not changed when these exceptions occur.

Depending on the model, the test for usability may be performed (1) by alternately storing and reading out test patterns to the data and storage key in the block or (2) by reference to an internal record of the usability of the blocks which are available in the configuration, or (3) by using a combination of both mechanisms.

In models in which an internal record is used, the block is indicated as unusable if a solid failure has been previously detected, or if intermittent failures in the block have exceeded the threshold implemented by the model. In such models, depending on the criteria, attempts to store may or may not occur. Thus, if block 0 is not usable, and no store occurs, low-address protection may or may not be indicated.

In models in which test patterns are used, TEST BLOCK may be interruptible. When an interruption occurs after a unit of operation, other than the last one, the condition code is unpredictable, and the contents of bit positions 32-63 of general register 0 may contain a record of the state of intermediate steps in the 24-bit or 31-bit addressing mode, or the contents of bit positions 0-63 may contain that record in the 64-bit addressing mode. When execution is resumed after an interruption, the condition code is ignored, but the record in general register 0 may be used to determine the resumption point.

If (1) TEST BLOCK is executed with an initial value other than zero in bit positions 32-63 of general register 0 in the 24-bit or 31-bit addressing mode or bit positions 0-63 in the 64-bit addressing mode, or (2) the interrupted instruction is resumed after an interruption with a value in bit positions 32-63 or 0-63 (depending on the addressing mode) of general register 0 or a value in the storage block or its associated storage key other than the corresponding value which was present at the time of the interruption, or (3) the block or its associated storage key is accessed by another CPU or by the channel subsystem during the execution of the instruction, then the contents of the storage block, its associated storage key, and bit positions 32-63 or 0-63 of general register 0 are unpredictable, along with the resultant condition-code setting.

Invalid checking-block-code errors initially found in the block or encountered during the test do not normally result in machine-check conditions. The test-block function is implemented in such a way that the frequency of machine-check interruptions due to the instruction execution is not significant. However, if, during the execution of TEST BLOCK for an unusable block, that block is accessed by another CPU (or by the channel subsystem), error conditions may be reported both to this CPU and to the other CPU (or to the channel subsystem).

A serialization function is performed before the block is accessed and again after the operation is completed (or partially completed).

The priority of the recognition of exceptions and condition codes is shown in Figure 10-64 on page 10-146.

#### **Resulting Condition Code:**

0 Block usable

- 1 Block not usable
- 2 --
- 3 --

**Program Exceptions:**

- Addressing (fetch and store, operand 2)
- Privileged operation
- Protection (store, operand 2, low-address protection only)

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Privileged-operation exception.
8.	Addressing exception due to block not being available in the configuration.*
9.A	Condition code 1, block not usable.
9.B	Protection exception due to low-address protection.*
10.	Condition code 0, block usable and set to zeros.

**Explanation:**

\* The operation is terminated on addressing and protection exceptions, and the condition code may be unpredictable.

Figure 10-64. Priority of Execution: TEST BLOCK

**Programming Notes:**

1. The execution of TEST BLOCK on most models is significantly slower than that of the MOVE LONG instruction with padding; therefore, the instruction should not be used for the normal case of clearing storage.
2. The program should use TEST BLOCK at initial program loading and as part of the vary-storage-online procedure to determine if blocks of storage exist which should not be used.
3. The program should use TEST BLOCK when an uncorrected error is reported in either the data or storage key of a block. This is because in the execution of TEST BLOCK the attempt is made, as far as is possible on the model, to leave the contents of a block in a state such that subsequent prefetches or unintended references to the

block do not cause machine-check conditions. The program may use the resulting condition code in this case to determine if the block can be reused. (The block could be indicated as usable if, for example, the error were an externally generated error or an indirect storage error.) This procedure should be followed regardless of whether the indirect-storage-error indication is reported.

4. The model may or may not be successful in removing the errors from a block when TEST BLOCK is executed. The program therefore should take every reasonable precaution to avoid referencing an unusable block. For example, the program should not place the page-frame real address of an unusable block in an attached and valid page-table entry.
5. On some models, machine checks may be reported for a block even though the block is not referenced by the program. When a machine check is reported for a storage-key error in a block which has been marked as unusable by the program, it is possible that SET STORAGE KEY EXTENDED may be more effective than TEST BLOCK in validating the storage key.
6. The storage-operand references for TEST BLOCK may be multiple-access references. (See "Storage-Operand Consistency" on page 5-95.)

## TEST PROTECTION

TPROT	D <sub>1</sub> (B <sub>1</sub> ),D <sub>2</sub> (B <sub>2</sub> )	[SSE]
'E501'	B <sub>1</sub> D <sub>1</sub> B <sub>2</sub> D <sub>2</sub>	0 16 20 32 36 47

The location designated by the first-operand address is tested for protection exceptions by using the access key specified by bits 56-59 of the second-operand address.

The second-operand address is not used to address data; instead, bits 56-59 of the address form the access key to be used in testing. Bits 0-55 and 60-63 of the second-operand address are ignored.

The first-operand address is a logical address. When the CPU is in the access-register mode (when DAT is on and PSW bits 16 and 17 are 01 binary), the first-operand address is subject to translation by means

of both the access-register-translation (ART) and the dynamic-address-translation (DAT) processes. ART applies to the access register designated by the  $B_1$  field, and it obtains the address-space-control element to be used by DAT. When DAT is on but the CPU is not in the access-register mode, the first-operand address is subject to translation by DAT. In this case, DAT uses the address-space-control element contained in control register 1, 7, or 13 when the CPU is in the primary-space, secondary-space, or home-space mode, respectively. When DAT is off, the first-operand address is a real address not subject to translation by either ART or DAT.

When the CPU is in the access-register mode and an address-space-control element cannot be obtained by ART because of a condition that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

Exception Name	Cause
ALET specification	Access-list-entry-token (ALET) bits 0-6 not all zeros
ALEN translation	Access-list entry (ALE) outside list or invalid (bit 0 is one)
ALE sequence	ALE sequence number (ALESN) in ALET not equal to ALESN in ALE
ASTE validity	ASN-second-table entry (ASTE) invalid (bit 0 is one)
ASTE sequence	ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE
Extended authority	ALE private bit not zero, ALE authorization index (ALEAX) not equal to extended authorization index (EAX), and secondary bit selected by EAX either outside authority table or zero

When the access register contains 00000000 hex or 00000001 hex, ART obtains the address-space-control element from control register 1 or 7, respectively, without accessing the access list. When the  $B_1$  field designates access register 0, ART treats the access register as containing 00000000 hex and does not examine the actual contents of the access register.

When ART is completed successfully, the operation is continued through the performance of DAT.

When DAT is on and the first-operand address cannot be translated because of a condition that would

normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

Exception Name	Cause
ASCE type	Address-space-control element (ASCE) being used is a region-second-table designation, and bits 0-10 of first-operand address not all zeros; ASCE is a region-third-table designation, and bits 0-21 of first-operand address not all zeros; or ASCE is a segment-table designation, and bits 0-32 of first-operand address not all zeros.
Region first translation	Region-first-table entry outside table or invalid.
Region second translation	Region-second-table entry outside table or invalid.
Region third translation	Region-third-table entry outside table or invalid.
Segment translation	Segment-table entry outside table or invalid
Page translation	Page-table entry invalid

When translation of the first-operand address can be completed, or when DAT is off, the storage key for the block designated by the first-operand address is tested against the access key specified in bit positions 56-59 of the second-operand address, and the condition code is set to indicate whether store and fetch accesses are permitted, taking into consideration all applicable protection mechanisms. Thus, for example, if low-address protection is active and the first-operand effective address is in the range 0-511 or 4096-4607, then a store access is not permitted. Access-list-controlled protection, DAT protection, storage-protection override, and fetch-protection override also are taken into account.

When enhanced DAT does not apply, or when enhanced DAT applies but the STE-format control is zero, bits 0-4 of the storage key for the 4K-byte block corresponding to the virtual address in the first operand are examined to determine the condition code. When enhanced DAT applies and the STE-format control is one, it is unpredictable whether bits 0-4 of the storage key or bits 48-52 of the segment-table entry used in the translation of the first operand are examined to determine the condition code.

The contents of storage, including the change bit, are not affected. Depending on the model, the reference bit for the first-operand address may be set to one, even for the case in which the location is protected against fetching.

### **Special Conditions**

When the CPU is in the access-register mode, an addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration.

When DAT is on, an addressing exception is recognized when the address of the region-table entry or entries, segment-table entry, or page-table entry or the operand real address after translation designates a location which is not available in the configuration. Also, a translation-specification exception is recognized when a region-table entry or the segment-table entry or page-table entry has a format error, that is, when any of the reasons listed in "Translation-Specification Exception" on page 6-39 applies. When DAT is off, only the addressing exception due to the operand real address applies.

For all of the above cases, the operation is suppressed.

### **Resulting Condition Code:**

- 0 Fetching permitted; storing permitted
- 1 Fetching permitted; storing not permitted
- 2 Fetching not permitted; storing not permitted
- 3 Translation not available

### **Program Exceptions:**

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, segment-table entry, page-table entry, or operand 1)
- Privileged operation
- Translation specification

### **Programming Notes:**

1. TEST PROTECTION permits a program to determine the protection attributes of an address passed from a calling program without incurring program exceptions. The instruction sets a condition code to indicate whether fetching or storing

is permitted at the location designated by the first-operand address of the instruction. The instruction takes into consideration all of the protection mechanisms in the machine: access-list controlled, DAT, key-controlled, and low-address protection, storage-protection override, and fetch-protection override. Additionally, since ASCE-type, region-translation, segment-translation, and page-translation-exception conditions may be a program substitute for a protection violation, these conditions are used to set the condition code rather than cause a program exception.

When the CPU is in the access-register mode, TEST PROTECTION additionally permits the program to check the usability of an access-list-entry token (ALET) in an access register without incurring program exceptions. The ALET is checked for validity (absence of an ALET-specification, ALEN-translation, and ALE-sequence-exception condition) and for being authorized for use by the program (absence of an ASTE-validity, ASTE-sequence, and extended-authority-exception condition).

2. See the programming notes under SET PSW KEY FROM ADDRESS for more details and for an alternative approach to testing the key-controlled protection attributes of addresses passed by a calling program. The approach using TEST PROTECTION has the advantage of a test which does not result in interruptions; however, the test and use are separated in time and may not be accurate if the possibility exists that the storage key of the location in question can change between the time it is tested and the time it is used.
3. In the handling of dynamic address translation, TEST PROTECTION is similar to LOAD REAL ADDRESS in that the instructions do not cause ASCE-type, region-translation, segment-translation, and page-translation exceptions. Instead, these exception conditions are indicated by means of a condition-code setting. Similarly, access-register translation sets a condition code for certain exception conditions when performed during either of the two instructions. Conditions which result in condition codes 1, 2, and 3 for LOAD REAL ADDRESS result in condition code 3 for TEST PROTECTION. The instructions also differ in several other respects. The first-operand address of TEST PROTECTION is a logical address and thus is not subject to dynamic address translation when DAT is off. The second-

operand address of LOAD REAL ADDRESS is a virtual address which is always translated.

Access-register translation applies to TEST PROTECTION only when the CPU is in the access-register mode (DAT is on), whereas it applies to LOAD REAL ADDRESS when PSW bits 16 and 17 are 01 binary regardless of whether DAT is on or off. When condition code 3 is set because of an exception condition in access-register translation, LOAD REAL ADDRESS, but not TEST PROTECTION, returns in a general register the program-interruption code assigned to the exception.

- Condition code 3 does not necessarily indicate that the first-operand location will always be inaccessible to the program; rather it merely indicates that the current conditions prevent the instruction from determining the protection attributes of the operand. For example, in a virtual storage environment, condition code 3 may be set if the storage location has been paged out by the operating system. If the program attempts to access the location, the operating system may resolve the page-translation exception and subsequently make the location accessible to the program.

Similarly, condition code 1 does not necessarily indicate that the address cannot ever be stored into. In an operating system that implements a Posix fork function, DAT protection is used to alert the operating system of a copy-on-write event (as described in Programming Note 1 on page 3-15). Following the operating-system resolution of the copy-on-write event, the program may be given store access to the location.

## TRACE

TRACE	R <sub>1</sub> ,R <sub>3</sub> ,D <sub>2</sub> (B <sub>2</sub> )	[RS]
'99'	R <sub>1</sub> R <sub>3</sub> B <sub>2</sub> D <sub>2</sub>	31

TRACG	R <sub>1</sub> ,R <sub>3</sub> ,D <sub>2</sub> (B <sub>2</sub> )	[RSY]
'EB'	R <sub>1</sub> R <sub>3</sub> B <sub>2</sub> DL <sub>2</sub> DH <sub>2</sub> '0F'	47

When explicit tracing is on (bit 63 of control register 12 is one), the second operand, which is a 32-bit word in storage, is fetched, and bit 0 of the word is

examined. If bit 0 of the second operand is zero, a trace entry is formed at the real-storage location designated by control register 12.

If explicit tracing is off (bit 63 of control register 12 is zero), or if bit 0 of the second operand is one, no trace entry is formed, and no trace exceptions are recognized.

The displacement for TRACE is treated as a 12-bit unsigned binary integer. The displacement for TRACG is treated as a 20-bit signed binary integer.

The trace entry is composed of an entry-type identifier, a count of the number of general registers whose partial or entire contents are placed in the entry, a field whose contents indicate whether the entry was formed by TRACE (TRACE) or TRACG (TRACG), selected bits of the TOD clock, the second operand, and the partial or entire contents of a range of general registers. For TRACE (TRACE), bits 16-63 of the TOD clock and bits 32-63 of the general registers are placed in the trace entry. For TRACE (TRACG), bits 0-79 of the clock and bits 0-63 of the registers are placed in the entry.

The general registers are stored in ascending order of their register numbers, starting with general register R<sub>1</sub> and continuing up to and including general register R<sub>3</sub>, with general register 0 following general register 15. The trace table and the trace-entry formats are described in "Tracing" on page 4-9.

When a trace entry is made, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store. Additionally, when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, it is unpredictable whether explicit tracing causes serialization to be performed.

## Special Conditions

A privileged-operation exception is recognized in the problem state, even when explicit tracing is off or bit 0 of the second operand is one.

The second operand must be designated on a word boundary; otherwise, a specification exception is rec-

ognized. It is unpredictable whether the specification exception is recognized when explicit tracing is off.

It is unpredictable whether access exceptions are recognized for the second operand when explicit tracing is off.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Trace

#### Programming Notes:

1. Bits 1-15 of the second operand are reserved for model-dependent functions and should therefore be set to zeros.
2. When the store-clock-fast facility is not installed, or when the TOD-clock-control in bit 32 of control register 0 is zero, the entire 32-bit TRACE operand is stored in bits 64-95 of the trace entry for TRACE (TRACE) and in bits 96-127 of the trace entry for TRACE (TRACG).
3. When the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, the following conditions apply:
  - Two executions of the instruction do not necessarily store different values in the TOD-clock bits of the trace entry.
  - The contents of bit positions 0-7 and 16-31 of the TRACE operand are stored in bits 64-71 and 80-95, respectively, of the trace entry for TRACE (TRACE) and in bits 96-103 and 112-127, respectively, of the trace entry for TRACE (TRACG).
  - Bits 72-79 of the trace entry for TRACE (TRACE) and bits 104-111 of the trace entry for TRACE (TRACG) are set to a model-dependent value.

## TRAP

TRAP2	[E]
'01FF'	
0	15

TRAP4	D <sub>2</sub> (B <sub>2</sub> )	[S]
'B2FF'	B <sub>2</sub>	D <sub>2</sub>
0	16	20

A trap operation is performed if the CPU is in the primary-space or access-register mode and the TRAP-enabled bit in byte 47 of the dispatchable-unit control table (DUCT) is one. Otherwise, a special-operation exception is recognized.

The trap operation obtains a trap-control-block address from the DUCT and then a trap-save-area address and a trap-program address from the trap control block. State information is stored in the trap save area. Then the trap-control-block address is loaded into general register 15. Finally, the current PSW is updated by setting the basic-addressing-mode bit to one (which will leave the addressing mode as either the 31-bit mode or the 64-bit mode or will change the addressing mode from the 24-bit mode to the 31-bit mode) and the address-space-control bits to zeros (primary-space mode) and by replacing the instruction address with the trap-program address. Compatibility with the ESA/390 operation of TRAP optionally is provided.

For TRAP4, the second-operand address is not used to address data; instead, bits 33-63 of the address are stored in the trap save area.

#### Dispatchable-Unit Control Table

Bytes 44-47 (word 10) of the dispatchable-unit-control table (DUCT) are used by this instruction. The contents of those bytes are as follows:

##### DUCT Bytes 44-47

	Trap-Control-Block Address	E
0 1		29 31

The fields in bytes 44-47 of the DUCT are allocated as follows:

**Trap-Control-Block Address:** Bits 1-28, with three zeros appended on the right, form the 31-bit home

virtual address of the trap control block. This address is treated as a 31-bit home virtual address regardless of the current addressing mode and regardless of the current value of the address-space-control bits. This address, with a zero appended on the left, is placed in bit positions 32-63 of general register 15 after the contents of that register have been saved in the trap save area. If the current addressing mode is the 64-bit mode, bits 0-31 of general register 15 are set to zeros.

**TRAP-Enabled Bit (E):** Bit 31 specifies, when one, that the trap operation is to be performed. TRAP recognizes a special-operation exception if bit 31 is zero.

Bits 0, 29, and 30 of bytes 44-47 are ignored, but they should be zeros to permit possible future extensions.

## Trap Control Block

The trap control block is 64 bytes aligned on a doubleword boundary. The format of the trap control block is:

The fields in the trap control block are allocated as follows:

**PSW Control (P):** Bit 13 of bytes 0-3 controls the allowed value of bit 31 of the current PSW and how bits 12 and 33-127 of the current PSW are stored in the PSW-values field in the trap save area. When bit 13 is zero.

- Bit 31 of the current PSW, the extended-addressing-mode bit, must be zero; otherwise, a special-operation exception is recognized.

- A one is stored in bit position 12 of the PSW-values field even though bit 12 of the current PSW is zero.
  - Bits 97-127 of the current PSW are stored in bit positions 33-63 of the PSW-values field, bits 33-96 of the current PSW are not stored, and zeros are stored in bit positions 64-127 of the PSW-values field.

When bit 13 is one:

- Bit 31 of the current PSW may be zero or one.
  - Bit 12 of the current PSW is stored in bit position 12 of the PSW-values field.
  - Bits 64-127 of the current PSW are stored in bit positions 64-127 of the PSW-values field.

**General-Registers Control (R):** Bit 14 of bytes 0-3 controls how the contents of the general registers are stored in the general-registers 0-15 field in the trap save area. When R is zero, bits 32-63 of the general registers are stored in consecutive four-byte locations beginning at the beginning of the general-registers 0-15 field, bits 0-31 of the registers are not stored, and the last 64 bytes of the general-registers 0-15 field remain unchanged. When R is one, bits 0-63 of the general registers are stored in consecutive eight-byte locations in the general-registers 0-15 field.

**Trap-Save-Area Address:** Bits 1-28 of bytes 12-15, with three zeros appended on the right, form the 31-bit home virtual address of the trap save area. This address is treated as a 31-bit home virtual address regardless of the current addressing mode and regardless of the current value of the address-space-control bits. Bits 0 and 29-31 of bytes 12-15 are ignored.

**Trap-Program Address:** Bits 1-31 of bytes 20-23 form the 31-bit primary virtual address of the trap program. This address is treated as a 31-bit primary virtual address regardless of the current addressing mode.

Bit positions 0-12 and 15-31 of bytes 0-3 and bytes 4-11, 16-19, and 32-63 of the trap control block are reserved and should contain zeros. Bytes 24-31 are available for use by programming.

## **Trap Save Area**

The trap save area is 256 bytes aligned on a double-word boundary.

The trap operation stores information into the trap save area as follows:

The fields in the trap save area are allocated as follows:

**Trap Flags:** Information identifying the instruction(s) causing the trap operation is stored in byte positions 0-3. The detailed format of bytes 0-3 is as follows:

<b>Flag Bits</b>	<b>Meaning</b>
0	TRAP was target of an execute-type instruction
1	TRAP is TRAP4 (not TRAP2)
2-12	Reserved, zeros stored
13-14	Instruction-length code (ILC)
15-31	Reserved, zeros stored

Bit 0 of bytes 0-3 is set to one if TRAP was the target of an execute-type instruction (EXECUTE or EXECUTE RELATIVE LONG).

Bit 1 of bytes 0-3 is set to one if TRAP is TRAP4 (not TRAP2).

Bits 13 and 14 are the instruction-length code (ILC) that specifies the length of the TRAP instruction, or the length of the execute-type instruction if TRAP was the target of an execute-type instruction.

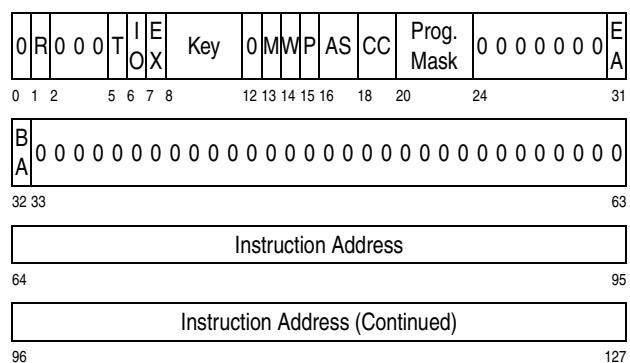

Bits 2-12 and 15-31 are reserved and are stored as zeros.

**Bits 33-63 of Second-Operand Address of TRAP4:** For TRAP4, bits 33-63 of the second-operand address, generated under the control of the current addressing mode and with a zero appended on the left, are stored in byte positions 8-11. Only bits 33-63 of the second-operand address are stored even when the current addressing mode is the 64-bit mode. For TRAP2, all zeros are stored in byte positions 8-11.

**Access Register 15:** The contents of access register 15 are stored in byte positions 12-15.

**PSW Values:** The following description applies when the PSW control, bit 13 of bytes 0-3 of the trap control block, is one.

Certain information from the current PSW is stored in byte positions 16-31. The PSW has the following format:

Bits 0-127 of bytes 16-31 correspond one-to-one with bits 0-127 of the PSW. For some bit positions of bytes 16-31, the corresponding PSW bits are stored. For the other bit positions of bytes 16-31, unpredictable values are stored. Information is stored in bytes 16-31 as follows:

<b>Bits</b>	<b>Value</b>
0	Zero
1	Unpredictable
2-4	Zero
5-11	Unpredictable

Bits	Value
12	Zero
13	Unpredictable
14	Wait state (W)
15	Problem state (P)
16-17	Address-space control (AS)
18-19	Condition code (CC)
20-23	Program mask
24-30	Zero
31	Extended addressing mode (EA)
32	Basic addressing mode (BA)
33-63	Zero
64-127	Instruction address

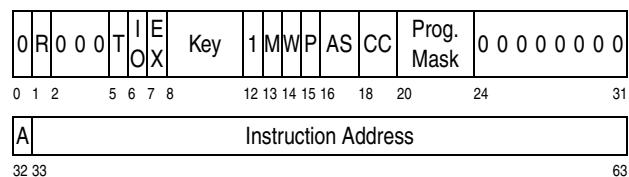

In summary, bits 0, 2-4, 12, 24-30, and 33-63 are zero, bits 1, 5-11, and 13 are unpredictable, and the other bits are set with variable information from the PSW.

The wait-state, problem-state, address-space-control, condition-code, program-mask, extended-addressing-mode, and basic-addressing-mode values specify the state of the CPU before the TRAP instruction was executed. The instruction-address value is the updated instruction address, which is the address of the instruction following TRAP, or the address of the instruction following the execute-type instruction if TRAP was the target of an execute-type instruction.

When the PSW control in the trap control block is zero, the operation is as described above except as follows:

- Bit 31 of the current PSW must be zero; otherwise, a special-operation exception is recognized.
- A one is stored in bit position 12 of bytes 16-31.
- Bits 97-127 of the current PSW are stored in bit positions 33-63 of bytes 16-31, bits 33-96 of the current PSW are not stored, and zeros are stored in bit positions 64-127 of bytes 16-31 (bytes 24-31).

In this case, bytes 16-23 have the format of an ESA/390 PSW, which is as follows:

**General Registers 0-15:** Contents of general registers 0-15 are stored in byte positions 32-159 as described in “General-Registers Control (R)” on page 10-151. When bits 32-63 or 0-63 of the general registers are stored, they are stored in ascending order of register numbers, starting with register 0 and continuing up to and including register 15.

Bytes 160-255 always remain unchanged. Bytes 168-255 are reserved. Bytes 160-167 are available for use by programming.

### Special Conditions

The CPU must be in the primary-space mode or access-register mode, and bit 31 in bytes 44-47 of the dispatchable-unit control table must be one; otherwise, a special-operation exception is recognized. A special-operation exception is also recognized if the PSW control, bit 13 of bytes 0-3 of the trap control block is zero and bit 31 of the current PSW, the extended-addressing-mode bit, is one.

All protection mechanisms apply in the usual way to the accesses to the trap control block and trap save area. Access exceptions may or may not be recognized for sections of the trap control block and trap save area that are not referenced by the TRAP instruction.

The trap-program address in the trap control block is not tested before it replaces the instruction address in the PSW. An odd address will cause a specification exception to be recognized as part of the execution of the next instruction.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-65 on page 10-154.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, trap control block; store, trap save area)
- Addressing (dispatchable-unit control table)
- Special operation
- Trace

**Programming Notes:**

1. It is intended that TRAP instructions will overlay instructions in an application program in order to give control to a trap program, which might be a program for performing fix-ups of data used by the application program, such as dates that may be a "Year-2000" problem. TRAP2 can overlay a two-byte instruction, and TRAP4 can overlay a four-byte instructions or the first four bytes of a six-byte instruction. The trap program is to simulate the overlaid instruction and perform fix-ups as appropriate, and it is then to return control to the application program.
2. The trap program can use the RESUME PROGRAM instruction to return control to the application program. For example, the trap program can restore the contents of all registers except
3. The trap control block and trap save area are in the home address space, and the trap program is in the primary address space. The trap-control-block address placed in general register 15 by TRAP can be useful to the trap program if (1) the primary address space and home address space are the same address space, (2) the trap control block and trap save area are at the same locations in the primary address space as in the home address space, or (3) the trap program can use access registers to access the home address space.
4. The storage-operand references for TRAP may be multiple-access references. (See "Storage-Operand Consistency" on page 5-95.)

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword (TRAP4 only).
7.B	Special-operation exception due to the CPU not being in the primary-space mode or access-register mode.
7.C.1	Addressing exception for access to dispatchable-unit control table.
7.C.2	Special-operation exception due to bit 31 in bytes 44-47 of dispatchable-unit control table being zero.
8.A	Trace exceptions.
8.B.1	Access exceptions (fetch) for trap control block.
8.B.2	Special-operation exception due to PSW control in trap control block being zero and PSW bit 31 being one.
8.B.3	Access exceptions (store) for trap save area.

Figure 10-65. Priority of Execution: TRAP

access and general registers 15, and then, using those registers (or at least the general register) to address the trap save area, can restore the contents of those registers and also PSW fields from the trap save area. RESUME PROGRAM has control bits in its parameter list that allow it to restore PSW fields from a field having either the ESA/390 PSW format or the z/Architecture PSW format and to restore either bits 32-63 or 0-63 of a general register.

The machine-check-handling mechanism provides extensive equipment-malfunction detection to ensure the integrity of system operation and to permit automatic recovery from some malfunctions. Equipment

malfunctions and certain external disturbances are reported by means of a machine-check interruption to assist in program-damage assessment and recovery. The interruption supplies the program with infor-

mation about the extent of the damage and the location and nature of the cause. Equipment malfunctions, errors, and other situations which can cause machine-check interruptions are referred to as machine checks.

---

## Machine-Check Detection

Machine-check-detection mechanisms may take many forms, especially in control functions for arithmetic and logical processing, addressing, sequencing, and execution. For program-addressable information, detection is normally accomplished by encoding redundancy into the information in such a manner that most failures in the retention or transmission of the information result in an invalid code. The encoding normally takes the form of one or more redundant bits, called check bits, appended to a group of data bits. Such a group of data bits and the associated check bits are called a checking block. The size of the checking block depends on the model.

The inclusion of a single check bit in the checking block allows the detection of any single-bit failure within the checking block. In this arrangement, the check bit is sometimes referred to as a "parity bit." In other arrangements, a group of check bits is included to permit detection of multiple errors, to permit error correction, or both.

For checking purposes, the contents of the entire checking block, including the redundancy, are called the checking-block code (CBC). When a CBC completely meets the checking requirements (that is, no failure is detected), it is said to be valid. When both detection and correction are provided and a CBC is not valid but satisfies the checking requirements for correction (the failure is correctable), it is said to be near-valid. When a CBC does not satisfy the checking requirements (the failure is uncorrectable), it is said to be invalid.

---

## Correction of Machine Malfunctions

Four mechanisms may be used to provide recovery from machine-detected malfunctions: error checking

and correction, CPU retry, channel-subsystem recovery, and unit deletion.

Machine failures which are corrected successfully may or may not be reported as machine-check interruptions. If reported, they are system-recovery conditions, which permit the program to note the cause of CPU delay and to keep a log of such incidents.

## Error Checking and Correction

When sufficient redundancy is included in circuitry or in a checking block, failures can be corrected. For example, circuitry can be triplicated, with a voting circuit to determine the correct value by selecting two matching results out of three, thus correcting a single failure. An arrangement for correction of failures of one order and for detection of failures of a higher order is called error checking and correction (ECC). Commonly, ECC allows correction of single-bit failures and detection of double-bit failures.

Depending on the model and the portion of the machine in which ECC is applied, correction may be reported as system recovery, or no report may be given.

Uncorrected errors in storage and in the storage key may be reported, along with a failing-storage address, to indicate where the error occurred. Depending on the situation, these errors may be reported along with system recovery or with the damage or backup condition resulting from the error.

## CPU Retry

In some models, information about some portion of the state of the machine is saved periodically. The point in the processing at which this information is saved is called a checkpoint. The information saved is referred to as the checkpoint information. The action of saving the information is referred to as establishing a checkpoint. The action of discarding previously saved information is called invalidation of the checkpoint information. The length of the interval between establishing checkpoints is model-dependent. Checkpoints may be established at the beginning of each instruction or several times within a single instruction, or checkpoints may be established less frequently.

Subsequently, this saved information may be used to restore the machine to the state that existed at the time when the checkpoint was established. After restoring the appropriate portion of the machine state, processing continues from the checkpoint. The process of restoring to a checkpoint and then continuing is called CPU retry.

CPU retry may be used for machine-check recovery, to effect nullification and suppression of instruction execution when certain program interruptions occur, and in other model-dependent situations.

### Effects of CPU Retry

CPU retry is, in general, performed so that there is no effect on the program. However, change bits which have been changed from zeros to ones are not necessarily set back to zeros. As a result, change bits may appear to be set to ones for blocks which would have been accessed if restoring to the checkpoint had not occurred. If the path taken by the program is dependent on information that may be changed by another CPU or by a channel program or if an interruption occurs, then the final path taken by the program may be different from the earlier path; therefore, change bits may be ones because of stores along a path apparently never taken.

### Checkpoint Synchronization

Checkpoint synchronization consists in the following steps.

1. The CPU operation is delayed until all conceptually previous accesses by this CPU to storage have been completed, both for purposes of machine-check detection and as observed by other CPUs and by channel programs.
2. All previous checkpoints, if any, are canceled.
3. Optionally, a new checkpoint is established.

The CPU operation is delayed until all of these actions appear to be completed, as observed by other CPUs and by channel programs.

### Handling of Machine Checks during Checkpoint Synchronization

When, in the process of completing all previous stores as part of the checkpoint-synchronization action, the machine is unable to complete all stores successfully but can successfully restore the machine to a previous checkpoint, processing backup is reported.

When, in the process of completing all stores as part of the checkpoint-synchronization action, the machine is unable to complete all stores successfully and cannot successfully restore the machine to a previous checkpoint, the type of machine-check-interruption condition reported depends on the origin of the store. Failure to successfully complete stores associated with instruction execution may be reported as instruction-processing damage, or some less critical machine-check-interruption condition may be reported with the storage-logical-validity bit set to zero. A failure to successfully complete stores associated with the execution of an interruption, other than program or supervisor call, is reported as system damage.

When the machine check occurs as part of a checkpoint-synchronization action before the execution of an instruction, the execution of the instruction is nullified. When it occurs before the execution of an interruption, the interruption condition, if the interruption is external, I/O, or restart, is held pending. If the checkpoint-synchronization operation was a machine-check interruption, then along with the originating condition, either the storage-logical-validity bit is set to zero or instruction-processing damage is also reported. Program interruptions, if any, are lost.

### Checkpoint-Synchronization Operations

All interruptions and the execution of certain instructions cause a checkpoint-synchronization action to be performed. The operations which cause a checkpoint-synchronization action are called checkpoint-synchronization operations and include:

- CPU reset
- All interruptions: external, I/O, machine check, program, restart, and supervisor call
- The BRANCH ON CONDITION (BCR) instruction with the M<sub>1</sub> and R<sub>2</sub> fields containing all ones and all zeros, respectively
- The instructions LOAD PSW, LOAD PSW EXTENDED, SET STORAGE KEY EXTENDED, and SUPERVISOR CALL
- All I/O instructions
- The instructions MOVE TO PRIMARY, MOVE TO SECONDARY, PROGRAM CALL, PROGRAM TRANSFER, SET ADDRESS SPACE CONTROL, and SET SECONDARY ASN, and PROGRAM RETURN when the state entry to be unstacked is a program-call state entry
- The four trace functions: branch tracing, ASN tracing, mode tracing, and explicit tracing, except that when the store-clock-fast facility is installed

and the TRACE TOD-clock control in bit 32 of control register 0 is one, then it is unpredictable whether explicit tracing causes a checkpoint-synchronization action.

- PAGE IN and PAGE OUT

**Programming Note:** The instructions which are defined to cause the checkpoint-synchronization action invalidate checkpoint information but do not necessarily establish a new checkpoint. Additionally, the CPU may establish a checkpoint between any two instructions or units of operation, or within a single unit of operation. Thus, the point of interruption for the machine check is not necessarily at an instruction defined to cause a checkpoint-synchronization action.

### Checkpoint-Synchronization Action

For all interruptions except I/O interruptions, a checkpoint-synchronization action is performed at the completion of the interruption. For I/O interruptions, a checkpoint-synchronization action may or may not be performed at the completion of the interruption. For all interruptions except program, supervisor-call, and exigent machine-check interruptions, a checkpoint-synchronization action is also performed before the interruption. The fetch access to the new PSW may be performed either before or after the first checkpoint-synchronization action. The store accesses and the changing of the current PSW associated with the interruption are performed after the first checkpoint-synchronization action and before the second.

For all checkpoint-synchronization instructions except BRANCH ON CONDITION (BCR), I/O instructions, and SUPERVISOR CALL, checkpoint-synchronization actions are performed before and after the execution of the instruction. For BCR, only one checkpoint-synchronization action is necessarily performed, and it may be performed either before or after the instruction address is updated. For SUPERVISOR CALL, a checkpoint-synchronization action is performed before the instruction is executed, including the updating of the instruction address in the PSW. The checkpoint-synchronization action taken after the supervisor-call interruption is considered to be part of the interruption action and not part of the instruction execution. For I/O instructions, a checkpoint-synchronization action is always performed

before the instruction is executed and may or may not be performed after the instruction is executed.

The four trace functions — branch tracing, ASN tracing, mode tracing, and explicit tracing — cause checkpoint-synchronization actions to be performed before the trace action and after completion of the trace action, except that when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, then it is unpredictable whether checkpoint-synchronization actions are performed for explicit tracing.

## Channel-Subsystem Recovery

When errors are detected in the channel subsystem, the channel subsystem attempts to analyze and recover the internal state associated with the various channel-subsystem functions and the state of the channel subsystem and various subchannels. This process, which is called channel-subsystem recovery, may result in a complete recovery or may result in the termination of one or more I/O operations and the clearing of the affected subchannels. Special channel-report-pending machine-check-interruption conditions may be generated to indicate to the program the status of the channel-subsystem recovery.

Malfunctions associated with the I/O operations, depending on the severity of the malfunction, may be reported by means of the I/O-interruption mechanism or by means of the channel-report-pending and channel-subsystem-damage machine-check-interruption conditions.

## Unit Deletion

In some models, malfunctions in certain units of the system can be circumvented by discontinuing the use of the unit. Examples of cases where unit deletion may occur include the disabling of all or a portion of a cache or of a translation-lookaside buffer (TLB). Unit deletion may be reported as a degradation machine-check-interruption condition.

## Handling of Machine Checks

A machine check is caused by a machine malfunction and not by data or instructions. This is ensured during the power-on sequence by initializing the

machine controls to a valid state and by placing valid CBC in the CPU registers, in the storage keys, and in main storage.

Designation of an unavailable component, such as a storage location, subchannel, or I/O device, does not cause a machine-check indication. Instead, such a condition is indicated by the appropriate program or I/O interruption or condition-code setting. In particular, an attempt to access a storage location which is not in the configuration, or which has power off at the storage unit, results in an addressing exception when detected by the CPU and does not generate a machine-check condition, even though the storage location or its associated storage key has invalid CBC. Similarly, if the channel subsystem attempts to access such a location, an I/O-interruption condition indicating program check is generated rather than a machine-check condition.

A machine check is indicated whenever the result of an operation could be affected by information with invalid CBC or when any other malfunction makes it impossible to establish reliably that an operation can be, or has been, performed correctly. When information with invalid CBC is fetched but not used, the condition may or may not be indicated, and the invalid CBC is preserved.

When a machine malfunction is detected, the action taken depends on the model, the nature of the malfunction, and the situation in which the malfunction occurs. Malfunctions affecting operator-facility actions may result in machine checks or may be indicated to the operator. Malfunctions affecting certain other operations such as SIGNAL PROCESSOR may be indicated by means of a condition code or may result in a machine-check-interruption condition.

A malfunction detected as part of an I/O operation may cause a machine-check-interruption condition, an I/O-error condition, or both. I/O-error conditions are indicated by an I/O interruption or by the appropriate condition-code setting during the execution of an I/O instruction. When the machine reports a failing-storage location detected during an I/O operation, both I/O-error and machine-check conditions may be indicated. The I/O-error condition is the primary indication to the program. The machine-check condition is a secondary indication, which is presented as system recovery together with a failing-storage address.

Certain malfunctions detected as part of I/O instructions and I/O operations are reported by means of special machine-check conditions called I/O machine-check conditions. Thus, malfunctions detected as part of an operation which is I/O related may be reported, depending on the error, in any of three ways: I/O-error condition, I/O machine-check condition, or non-I/O machine-check condition. In some cases, the definition requires the error to be reported by only one of these mechanisms; in other cases, any one, or in some cases, more than one, may be indicated.

**Programming Note:** Although the definition for machine-check conditions is that they are caused by machine malfunctions and not by data and instructions, there are certain unusual situations in which machine-check conditions are caused by events which are not machine malfunctions. Two examples follow:

1. In some cases, the channel-report-pending machine-check-interruption condition indicates a non-error situation. For example, this condition is generated at the completion of the function specified by RESET CHANNEL PATH.
2. Improper use of DIAGNOSE may result in machine-check conditions.

## Validation

Machine errors can be generally classified as solid or intermittent, according to the persistence of the malfunction. A persistent machine error is said to be solid, and one that is not persistent is said to be intermittent. In the case of a register or storage location, a third type of error must be considered, called externally generated. An externally generated error is one where no failure exists in the register or storage location but invalid CBC has been introduced into the location by actions external to the location. For example, the value could be affected by a power transient, or an incorrect value may have been introduced when the information was placed at the location.

Invalid CBC is preserved as invalid when information with invalid CBC is fetched or when an attempt is made to update only a portion of the checking block. When an attempt is made to replace the contents of the entire checking block and the block contains invalid CBC, it depends on the operation and the model whether the block remains with invalid CBC or

is replaced. An operation which replaces the contents of a checking block with valid CBC, while ignoring the current contents, is called a validation operation. Validation is used to place a valid CBC in a register or at a location which has an intermittent or externally generated error.

Validating a checking block does not ensure that a valid CBC will be observed the next time the checking block is accessed. If the failure is solid, validation is effective only if the information placed in the checking block is such that the failing bits are set to the value to which they fail. If an attempt is made to set the bits to the state opposite to that in which they fail, then the validation will not be effective. Thus, for a solid failure, validation is only useful to eliminate the error condition, even though the underlying failure remains, thereby reducing the exposure to additional reports. The locations, however, cannot be used, since invalid CBC will result from attempts to store other values at the location. For an intermittent failure, however, validation is useful to restore a valid CBC such that a subsequent partial store into the checking block will be permitted. (A partial store is a store into a checking block without replacing the entire checking block.)

When a checking block consists of multiple bytes in storage, or multiple bits in CPU registers, the invalid CBC can be made valid only when all of the bytes or bits are replaced simultaneously.

For each type of field in the system, certain instructions are defined to validate the field. Depending on the model, additional instructions may also perform validation; or, in some models, a register is automatically validated as part of the machine-check-interruption sequence after the original contents of the register are placed in the appropriate save area.

When an error occurs in a checking block, the original information contained in the checking block should be considered lost even after validation. Automatic register validation leaves the contents unpredictable. Programmed and manual validation of checking blocks causes the contents to be changed explicitly.

**Programming Note:** The machine-check-interruption handler must assume that the registers require validation. Thus, each register should be loaded, using an instruction defined to validate, before the register is used or stored.

## Invalid CBC in Storage

The size of the checking block in storage depends on the model but is never more than 4K bytes.

When invalid CBC is detected in storage, a machine-check condition may occur; depending on the circumstances, the machine-check condition may be system damage, instruction-processing damage, or system recovery. If the invalid CBC is detected as part of the execution of a channel program, the error is reported as an I/O-error condition. When a CCW, indirect-data-address word, modified-indirect-data-address word, or data is prefetched from storage, is found to have invalid CBC, but is not used in the channel program, the condition is normally not reported as an I/O-error condition. The condition may or may not be reported as a machine-check-interruption condition. Invalid CBC detected during accesses to storage for other than CPU-related accesses may be reported as system recovery with storage error uncorrected indicated, since the primary error indication is reported by some other means.

When the storage checking block consists of multiple bytes and contains invalid CBC, special storage-validation procedures are generally necessary to restore or place new information in the checking block. Validation of storage is provided with the manual load-clear and system-reset-clear operations and is also provided as a program function. Programmed storage validation is done a block at a time, by executing the privileged instruction TEST BLOCK. Manual storage validation by clear reset validates all blocks which are available in the configuration.

A checking block with invalid CBC is never validated unless the entire contents of the checking block are replaced. An attempt to store into a checking block having invalid CBC, without replacing the entire checking block, leaves the data in the checking block (including the check bits) unchanged. Even when an instruction or a channel-program-input operation specifies that the entire contents of a checking block are to be replaced, validation may or may not occur, depending on the operation and the model.

**Programming Note:** Machine-check conditions may be reported for prefetched and unused data. Depending on the model, such situations may or may not be successfully retried. For example, a BRANCH AND LINK (BALR) instruction which specifies an R<sub>2</sub> field of zero will never branch, but on some models a

prefetch of the location designated by register 0 may occur. Access exceptions associated with this prefetch will not be reported. However, if an invalid checking-block code is detected, CPU retry may be attempted. Depending on the model, the prefetch may recur as part of the retry, and thus the retry will not be successful. Even when the CPU retry is successful, the performance degradation of such a retry is significant, and system recovery may be presented, normally with a failing-storage address. To avoid continued degradation, the program should initiate proceedings to eliminate use of the location and to validate the location.

### **Programmed Validation of Storage**

Provided that an invalid CBC does not exist in the storage key associated with a 4K-byte block, the instruction TEST BLOCK causes the entire 4K-byte block to be set to zeros with a valid CBC, regardless of the current contents of the storage. TEST BLOCK thus removes an invalid CBC from a location in storage which has an intermittent, or one-time, failure. However, if a permanent failure exists in a portion of the storage, a subsequent fetch may find an invalid CBC.

### **Invalid CBC in Storage Keys**

Depending on the model, each storage key may be contained in a single checking block, or the access-control and fetch-protection bits and the reference and change bits may be in separate checking blocks.

Figure 11-1 on page 11-7 describes the action taken when the storage key has invalid CBC. The figure indicates the action taken for the case when the access-control and fetch-protection bits are in one checking block and the reference and change bits are in a separate checking block. In machines where both fields are included in a single checking block, the action taken is the combination of the actions for each field in error, except that completion is permitted only if an error in all affected fields permits completion. References to main storage to which key-controlled protection does not apply are treated as if an access key of zero is used for the reference. This includes such references as channel-program references during initial program loading and implicit references, such as interruption action and DAT-table accesses.

<b>Type of Reference</b>	<b>Action Taken on Invalid CBC</b>	
	<b>For Access-Control and Fetch-Protection Bits</b>	<b>For Reference and Change Bits</b>
SET STORAGE KEY EXTENDED	Complete; validate.	Complete; validate.
INSERT STORAGE KEY EXTENDED	PD; preserve.	PD; preserve.
RESET REFERENCE BIT EXTENDED	PD or complete; preserve.	PD; preserve.
INSERT VIRTUAL STORAGE KEY or TEST PROTECTION	PD; preserve.	CPF; preserve.
CPU prefetch (information not used)	CPF; preserve.	CPF; preserve.
Channel-program prefetch (information not used)	IPF; preserve.	IPF; preserve.
Fetch, nonzero access key	MC; preserve.	MC or complete; preserve.
Store <sup>1</sup> , nonzero access key	MC <sup>2</sup> ; preserve.	MC and preserve; or complete <sup>3</sup> and correct.
Fetch, zero access key <sup>4</sup>	MC or complete; preserve.	MC or complete; preserve.
Store <sup>1</sup> , zero access key <sup>2</sup>	MC or complete; preserve.	MC and preserve; or complete <sup>3</sup> and correct.

Figure 11-1. Invalid CBC in Storage Keys (Part 1 of 2)

**Explanation:**

1	CPU virtual- and logical-address store accesses are subject to DAT protection. When the DAT-protection bit is one, the location will not be changed; however, the machine may indicate a machine-check condition if the storage key or the data itself has invalid CBC.
2	The contents of the main-storage location are not changed.
3	The contents of the reference and change bits are set to ones if the "complete" action is taken.
4	The action shown for an access key of zero is also applicable to references to which key-controlled protection does not apply.
Complete	The condition does not cause termination of the execution of the instruction, and, unless an unrelated condition prohibits it, the execution of the instruction is completed, ignoring the error condition. No machine- check-damage conditions are reported, but system recovery may be reported.
Correct	The reference and change bits are set to ones with valid CBC.
Preserve	The contents of the entire checking block having invalid CBC are left unchanged.
Validate	The entire key is set to the new value with valid CBC. When the conditional-SSKE facility is installed and either or both the MR and MC bits of the M <sub>3</sub> field are one, condition code 3 is set when the instruction completes.
CPF	Invalid CBC in the storage key for a CPU prefetch which is unused, or for instructions which do not examine the reference and change bits, may result in any of the following situations: <ul style="list-style-type: none"><li>• The operation is completed; no machine-check condition is reported.</li><li>• The operation is completed; system recovery, with storage-key error uncorrected, is reported.</li><li>• Instruction-processing damage, with or without backup and with storage-key error uncorrected, is reported.</li></ul>
IPF	Invalid CBC in the storage key for a channel-program prefetch which is unused may result in any of the following: <ul style="list-style-type: none"><li>• The I/O operation is completed; no machine-check condition is reported.</li><li>• The I/O operation is completed; system recovery, with storage-key error uncorrected, is reported.</li></ul>
MC	Same as PD for CPU references, but a channel-subsystem reference may result in the following combinations of I/O-error conditions and machine-check conditions: <ul style="list-style-type: none"><li>• An I/O-error condition is reported; no machine-check condition is reported.</li><li>• An I/O-error condition is reported; system recovery, with or without storage-key error uncorrected, is reported.</li></ul>
PD	Instruction-processing damage, with or without backup and with or without storage-key error uncorrected, is reported.
<b>Note:</b>	When storage-key error uncorrected is reported, a failing storage address may or may not also be reported.

Figure 11-1. Invalid CBC in Storage Keys (Part 2 of 2)

## Invalid CBC in Registers

When invalid CBC is detected in a CPU register, a machine-check condition may be recognized. CPU registers include the general, floating-point, floating-point-control, access, control, and TOD programmable registers, the current PSW, the prefix register, the TOD clock, the CPU timer, and the clock comparator.

When a machine-check interruption occurs, whether or not it is due to invalid CBC in a CPU register, the following actions affecting the CPU registers, other than the prefix register and the TOD clock, are taken as part of the interruption.

1. The contents of the registers are saved in assigned storage locations. Any register which is in error is identified by a corresponding validity bit of zero in the machine-check-interruption code. Malfunctions detected during register saving do not result in additional machine-check-interruption conditions; instead, the correctness

of all the information stored is indicated by the appropriate setting of the validity bits.

2. On some models, registers with invalid CBC are then validated, their actual contents being unpredictable. On other models, programmed validation is required.

The prefix register and the TOD clock are not stored during a machine-check interruption, have no corresponding validity bit, and are not validated.

On those models in which registers are not automatically validated as part of the machine-check interruption, a register with invalid CBC will not cause a machine-check-interruption condition unless the contents of the register are actually used. In these models, each register may consist of one or more checking blocks, but multiple registers are not included in a single checking block. When only a portion of a register is accessed, invalid CBC in the unused portion of the same register may cause a

machine-check-interruption condition. For example, invalid CBC in the right half of a floating-point register may cause a machine-check-interruption condition if a LOAD (LE) operation attempts to replace the left half, or short form, of the register.

Invalid CBC associated with the prefix register cannot safely be reported by the machine-check interruption, since the interruption itself requires that the prefix value be applied to convert real addresses to the corresponding absolute addresses. Invalid CBC in the prefix register causes the CPU to enter the check-stop state immediately.

On those models which do not validate registers during a machine-check interruption, the following instructions will cause validation of a register, provided the information in the register is not used before the register is validated. Other instructions, although they replace the entire contents of a register, do not necessarily cause validation.

General registers are validated by BRANCH AND SAVE and LOAD ADDRESS executed in the 64-bit addressing mode, by LOAD (LGR), and by LOAD (LG) and LOAD MULTIPLE (LMG) if the operand is on a doubleword boundary.

Floating-point registers are validated by LOAD (LDR) and, if the operand is on a doubleword boundary, by LOAD (LD).

The floating-point-control register is validated by LOAD FLOATING POINT CONTROL REGISTER.

Access registers are validated by LOAD ACCESS MULTIPLE. Only the even-odd access-register pairs that are included in the set of access registers specified for LOAD ACCESS MULTIPLE are validated. Thus, when a single access register is specified, or when a pair of access registers starting with an odd-numbered register is specified, no register is validated.

Control registers may be validated either singly or in groups by using the instruction LOAD CONTROL (LCTLG).

The TOD programmable register, CPU timer, clock comparator, and prefix register are validated by SET CLOCK PROGRAMMABLE REGISTER, SET CPU TIMER, SET CLOCK COMPARATOR, and SET PREFIX, respectively.

The TOD clock is validated by a SET CLOCK instruction that sets the clock.

**Programming Note:** Depending on the register and the model, the contents of a register may be validated by the machine-check interruption, or the model may require that a program execute a validating instruction after the machine-check interruption has occurred. In the case of the CPU timer, depending on the model, both the machine-check interruption and validating instructions may be required to restore the CPU timer to full working order.

---

## Check-Stop State

In certain situations, it is impossible or undesirable to continue operation when a machine error occurs. In these cases, the CPU may enter the check-stop state, which is indicated by the check-stop indicator.

In general, the CPU may enter the check-stop state whenever an uncorrectable error or other malfunction occurs and the machine is unable to recognize a specific machine-check-interruption condition.

The CPU always enters the check-stop state if any of the following conditions exists:

- PSW bit 13 is zero, and an exigent machine-check condition is generated.
- During the execution of an interruption due to one exigent machine-check condition, another exigent machine-check condition is detected.
- During a machine-check interruption, the machine-check-interruption code cannot be stored successfully, or the new PSW cannot be fetched successfully.
- Invalid CBC is detected in the prefix register.
- A malfunction in the receiving CPU, which is detected after accepting the order, prevents the successful completion of a SIGNAL PROCESSOR order and the order was a reset, or the receiving CPU cannot determine what the order was. The receiving CPU enters the check-stop state.

There may be many other conditions for particular models when an error may cause check stop.

When the CPU is in the check-stop state, instructions and interruptions are not executed. The TOD clock is normally not affected by the check-stop state. The CPU timer may or may not run in the check-stop state, depending on the error and the model. The start key and stop key are not effective in this state.

The CPU may be removed from the check-stop state by CPU reset.

In a multiprocessing configuration, a CPU entering the check-stop state generates a request for a malfunction-alert external interruption to all CPUs in the configuration. Except for the reception of a malfunction alert, other CPUs and the I/O system are normally unaffected by the check-stop state in a CPU. However, depending on the nature of the condition causing the check stop, other CPUs may also be delayed or stopped, and channel subsystem and I/O activity may be affected.

### **System Check Stop**

In a multiprocessing configuration, some errors, malfunctions, and damage conditions are of such severity that the condition causes all CPUs in the configuration to enter the check-stop state. This condition is called a system check stop. The state of the channel subsystem and I/O activity is unpredictable.

---

## **Machine-Check Interruption**

A request for a machine-check interruption, which is made pending as the result of a machine check, is called a machine-check-interruption condition. There are two types of machine-check-interruption conditions: exigent conditions and repressible conditions.

### **Exigent Conditions**

Exigent machine-check-interruption conditions are those in which damage has or would have occurred such that execution of the current instruction or interruption sequence cannot safely continue. Exigent conditions include two subclasses: instruction-processing damage and system damage. In addition to indicating specific exigent conditions, system damage is used to report any malfunction or error which cannot be isolated to a less severe report.

Exigent conditions for instruction sequences can be either nullifying exigent conditions or terminating exigent conditions, according to whether the instructions affected are nullified or terminated. Exigent conditions for interruption sequences are terminating exigent conditions. The terms “nullification” and “termination” have the same meanings as those used in Chapter 5, “Program Execution”, except that more than one instruction may be involved. Thus, a nullifying exigent condition indicates that the CPU has returned to the beginning of a unit of operation prior to the error. A terminating exigent condition means that the results of one or more instructions may have unpredictable values.

### **Repressible Conditions**

Repressible machine-check-interruption conditions are those in which the results of the instruction-processing sequence have not been affected. Repressible conditions can be delayed, until the completion of the current instruction or even longer, without affecting the integrity of CPU operation. Repressible conditions are of three groups: recovery, alert, and repressible damage. Each group includes one or more subclasses.

A malfunction in the CPU, storage, or operator facilities which has been successfully corrected or circumvented internally without logical damage is called a recovery condition. Depending on the model and the type of malfunction, some or all recovery conditions may be discarded and not reported. Recovery conditions that are reported are grouped in one subclass, system recovery.

A machine-check-interruption condition not directly related to a machine malfunction is called an alert condition. The alert conditions are grouped in two subclasses: degradation and warning.

A malfunction resulting in an incorrect state of a portion of the system not directly affecting sequential CPU operation is called a repressible-damage condition. Repressible-damage conditions are grouped in five subclasses, according to the function affected: timing-facility damage, external damage, channel report pending, channel-subsystem damage, and service-processor damage.

### Programming Notes:

1. Even though repressible conditions are usually reported only at normal points of interruption, they may also be reported with exigent machine-check conditions. Thus, if an exigent machine-check condition causes an instruction to be abnormally terminated and a machine-check interruption occurs to report the exigent condition, any pending repressible conditions may also be reported. The meaningfulness of the validity bits depends on what exigent condition is reported.
2. Classification of damage as either exigent or repressible does not imply the severity of the damage. The distinction is whether action must be taken as soon as the damage is detected (exigent) or whether the CPU can continue processing (repressible). For a repressible condition, the current instruction can be completed before taking the machine-check interruption if the CPU is enabled for machine checks; if the CPU is disabled for machine checks, the condition can safely be kept pending until the CPU is again enabled for machine checks.

For example, the CPU may be disabled for machine-check interruptions because it is handling an earlier instruction-processing-damage interruption. If, during that time, an I/O operation encounters a storage error, that condition can be kept pending because it is not expected to interfere with the current machine-check processing. If, however, the CPU also makes a reference to the area of storage containing the error before re-enabling machine-check interruptions, another instruction-processing-damage condition is created, which is treated as an exigent condition and causes the CPU to enter the check-stop state.

3. A repressible condition may be a floating condition. A floating repressible condition is eligible to cause an interruption on any CPU in the configuration. At the point when a CPU performs an interruption for a floating repressible condition, the condition is no longer eligible to cause an interruption on the remaining CPUs in the configuration.

### Interruption Action

A machine-check interruption causes the following actions to be taken. An architectural-mode identification with the value 01 hex is stored at real location 163. The PSW reflecting the point of interruption is stored as the machine-check old PSW in the quad-word at real location 352. The contents of other registers are stored in register-save areas at real locations 4608-4863, 4892-4895, 4900-4911, 4913-4919, and 4928-5119. After the contents of the registers are stored in register-save areas, depending on the model, the registers may be validated with the contents being unpredictable. A machine-check-interruption code (MCIC) of eight bytes is stored at real locations 232-239. An external-damage code may be stored at real locations 244-247, and a failing-storage address may be stored at real locations 248-255. The new PSW is fetched from real locations 480-495. In addition, a machine-check logout may have occurred.

The machine-generated addresses used to access the old and new PSW, the MCIC, extended interruption information, and the fixed-logout area are all real addresses.

The fields in assigned storage locations that are accessed during the machine-check interruption are summarized in Figure 11-2.

Information Stored (Fetched)	Starting Location*	Length in Bytes
Architectural-mode identification	163	1
Old PSW	352	16
New PSW (fetched)	480	16
Machine-check-interruption code	232	8
Register-save areas		
Floating-point registers 0-15	4608	128
General registers 0-15	4736	128
Floating-point control register	4892	4
TOD programmable register	4900	4
CPU timer	4904	8
Clock comparator	4913	7
Access registers 0-15	4928	64
Control registers 0-15	4992	128
Extended interruption information		

Figure 11-2. Machine-Check-Interrupt Locations

<b>Information Stored (Fetched)</b>	<b>Starting Location*</b>	<b>Length in Bytes</b>
External-damage code	244	4
Failing-storage address	248	8
Fixed-logout area	4864	16
<b>Explanation:</b>		
* All locations are in real storage.		

Figure 11-2. Machine-Check-Interrupt Locations

If the machine-check-interruption code cannot be stored successfully or the new PSW cannot be fetched successfully, the CPU enters the check-stop state.

A repressible machine-check condition can initiate a machine-check interruption only if both PSW bit 13 is one and the associated subclass mask bit, if any, in control register 14 is also one. When it occurs, the interruption does not terminate the execution of the current instruction; the interruption is taken at a normal point of interruption, and no program or supervisor-call interruptions are eliminated. If the machine check occurs during the execution of a machine function, such as a CPU-timer update, the machine-check interruption takes place after the machine function has been completed.

When the CPU is disabled for a particular repressible machine-check condition, the condition remains pending. Depending on the model and the condition, multiple repressible conditions may be held pending for a particular subclass, or only one condition may be held pending for a particular subclass, regardless of the number of conditions that may have been detected for that subclass.

When a repressible machine-check interruption occurs because the interruption condition is in a subclass for which the CPU is enabled, pending conditions in other subclasses may also be indicated by the same interruption code, even though the CPU is disabled for those subclasses. All indicated conditions are then cleared.

If a machine check which is to be reported as a system-recovery condition is detected during the execution of the interruption procedure due to a previous machine-check condition, the system-recovery condition may be combined with the other conditions, discarded, or held pending.

An exigent machine-check condition can cause a machine-check interruption only when PSW bit 13 is one. When a nullifying exigent condition causes a machine-check interruption, the interruption is taken at a normal point of interruption. When a terminating exigent condition causes a machine-check interruption, the interruption terminates the execution of the current instruction and may eliminate the program and supervisor-call interruptions, if any, that would have occurred if execution had continued. Proper execution of the interruption sequence, including the storing of the old PSW and other information, depends on the nature of the malfunction. When an exigent machine-check condition occurs during the execution of a machine function, such as a CPU-timer update, the sequence is not necessarily completed.

If, during the execution of an interruption due to one exigent machine-check condition, another exigent machine check is detected, the CPU enters the check-stop state. If an exigent machine check is detected during an interruption due to a repressible machine-check condition, system damage is reported.

When PSW bit 13 is zero, an exigent machine-check condition causes the CPU to enter the check-stop state.

Machine-check-interruption conditions are handled in the same manner regardless of whether the wait-state bit in the PSW is one or zero: a machine-check condition causes an interruption if the CPU is enabled for that condition.

Machine checks which occur while the rate control is set to the instruction-step position are handled in the same manner as when the control is set to the process position; that is, recovery mechanisms are active, and machine-check interruptions occur when allowed. Machine checks occurring during a manual operation may be indicated to the operator, may generate a system-recovery condition, may result in system damage, or may cause a check stop, depending on the model.

Every reasonable attempt is made to limit the side effects of any machine check and the associated interruption. Normally, interruptions, as well as the progress of I/O operations, remain unaffected. The malfunction, however, may affect these activities, and, if the currently active PSW has bit 13 set to one, the machine-check interruption will indicate the total

extent of the damage caused, and not just the damage which originated the condition.

## Point of Interruption

The point in the processing which is indicated by the interruption and used as a reference point by the machine to determine and indicate the validity of the status stored is referred to as the point of interruption.

Because of the checkpoint capability in models with CPU retry, the interruption resulting from an exigent machine-check-interruption condition may indicate a point in the CPU processing sequence which is logically prior to the error. Additionally, the model may have some choice as to which point in the CPU processing sequence the interruption is indicated, and, in some cases, the status which can be indicated as valid depends on the point chosen.

Only certain points in the processing may be used as a point of interruption. For repressible machine-check interruptions, the point of interruption must be after one unit of operation is completed and any associated program or supervisor-call interruption is taken, and before the next unit of operation is begun.

Exigent machine-check conditions for instruction sequences are those in which damage has or would have occurred to the instruction stream. Thus, the damage can normally be associated with a point part way through an instruction, and this point is called the point of damage. In some cases, there may be one or more instructions separating the point of damage and the point of interruption, and the processing associated with one or more instructions may be damaged. When the point of interruption is a point prior to the point of damage due to a nullifiable exigent machine-check condition, the point of interruption can be only at the same points as for repressible machine-check conditions.

In addition to the point of interruption permitted for repressible machine-check conditions, the point of interruption for a terminating exigent machine-check

condition may also be after the unit of operation is completed but before any associated program or supervisor-call interruption occurs. In this case, a valid PSW instruction address is defined as that which would have been stored in the old PSW for the program or supervisor-call interruption. Since the operation has been terminated, the values in the result fields, other than the instruction address, are unpredictable. Thus, the validity bits associated with fields which are due to be changed by the instruction stream are meaningless when a terminating exigent machine-check condition is reported.

When the point of interruption and the point of damage due to an exigent machine-check condition are separated by a checkpoint-synchronization function, the damage has not been isolated to a particular program, and system damage is indicated.

When an exigent machine-check-interruption condition occurs, the point of interruption which is chosen affects the amount of damage which must be indicated. An attempt is made, when possible, to choose a point of interruption which permits the minimum indication of damage. In general, the preference is the interruption point immediately preceding the error.

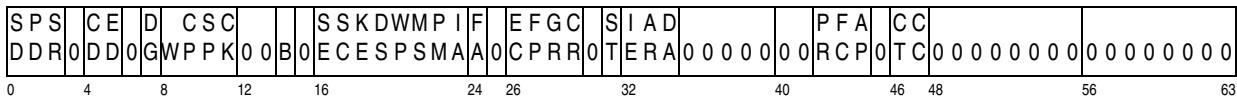

When all the status information stored as a result of an exigent machine-check-interruption condition does not reflect the same point, an attempt is made, when possible, to choose the point of interruption so that the instruction address which is stored in the machine-check old PSW is valid.

---

## Machine-Check-Interruption Code

On all machine-check interruptions, a machine-check-interruption code (MCIC) is stored in the doubleword starting at real location 232. The code has the format shown in Figure 11-3.

Bits in the MCIC which are not assigned or not implemented by a particular model are stored as zeros.

Bits    Name

- 0 System damage (SD)
- 1 Instruction-processing damage (PD)
- 2 System recovery (SR)
- 4 Timing-facility damage (CD)
- 5 External damage (ED)
- 7 Degradation (DG)
- 8 Warning (W)
- 9 Channel report pending (CP)
- 10 Service-processor damage (SP)
- 11 Channel-subsystem damage (CK)
- 14 Backed up (B)
- 16 Storage error uncorrected (SE)
- 17 Storage error corrected (SC)
- 18 Storage-key error uncorrected (KE)
- 19 Storage degradation (DS)
- 20 PSW-MWP validity (WP)
- 21 PSW mask and key validity (MS)
- 22 PSW program-mask and condition-code validity (PM)
- 23 PSW-instruction-address validity (IA)
- 24 Failing-storage-address validity (FA)
- 26 External-damage-code validity (EC)
- 27 Floating-point-register validity (FP)
- 28 General-register validity (GR)
- 29 Control-register validity (CR)
- 31 Storage logical validity (ST)
- 32 Indirect storage error (IE)
- 33 Access-register validity (AR)
- 34 Delayed-access exception (DA)
- 42 TOD-programmable-register validity (PR)
- 43 Floating-point-control-register validity (FC)
- 44 Ancillary report (AP)
- 46 CPU-timer validity (CT)
- 47 Clock-comparator validity (CC)

**Note:** All other bits of the MCIC are unassigned and stored as zeros.

Figure 11-3. Machine-Check Interruption-Code Format

## Subclass

Bits 0-2 and 4-11 are the subclass bits which identify the type of machine-check condition causing the interruption. At least one of the subclass bits is stored as a one. When multiple errors have occurred, several subclass bits may be set to ones.

## System Damage

Bit 0 (SD), when one, indicates that damage has occurred which cannot be isolated to one or more of the less severe machine-check subclasses. When system damage is indicated, the ancillary-report bit, bit 44, is meaningful, the remaining bits in the machine-check-interruption code are not meaningful, and information stored in the register-save areas and

machine-check extended-interruption fields is not meaningful.

System damage is a terminating exigent condition and has no subclass-mask bit.

### Instruction-Processing Damage

Bit 1 (PD), when one, indicates that damage has occurred to the instruction processing of the CPU.

The exact meaning of bit 1 depends on the setting of the backed-up bit, bit 14. When the backed-up bit is one, the condition is called processing backup. When the backed-up bit is zero, the condition is called processing damage. These two conditions are described in “Synchronous Machine-Check-Interruption Conditions” on page 11-17.

Instruction-processing damage can be a nullifying or a terminating exigent condition and has no subclass-mask bit.

### System Recovery

Bit 2 (SR), when one, indicates that malfunctions were detected but did not result in damage or have been successfully corrected. Some malfunctions detected as part of an I/O operation may result in a system-recovery condition in addition to an I/O-error condition. The presence and extent of the system-recovery capability depend on the model.

System recovery is a repressible condition. It is masked by the recovery subclass-mask bit, which is in bit position 36 of control register 14.

#### Programming Notes:

1. System recovery may be used to report a failing storage address detected by a CPU prefetch or by an I/O operation.
2. Unless the corresponding validity bits are ones, the indication of system recovery does not imply storage logical validity or that the fields stored as a result of the machine-check interruption are valid.

### Timing-Facility Damage

Bit 4 (CD), when one, indicates that damage has occurred to the TOD clock, CPU timer, clock comparator, or TOD programmable register, or to the CPU-timer or clock-comparator external-interruption condi-

tions. The timing-facility-damage machine-check condition is set whenever any of the following occurs:

1. The TOD clock enters the error or not-operational state.
2. The CPU timer is damaged, and the CPU is enabled for CPU-timer external interruptions. On some models, this condition may be recognized even when the CPU is not enabled for CPU-timer interruptions. Depending on the model, the machine-check condition may be generated only as the CPU timer enters an error state. Or, the machine-check condition may be continuously generated whenever the CPU is enabled for CPU-timer interruptions, until the CPU timer is validated.
3. The clock comparator is damaged, and the CPU is enabled for clock-comparator external interruptions. On some models, this condition may be recognized even when the CPU is not enabled for clock-comparator interruptions.

Timing-facility damage may also be set along with instruction-processing damage when an instruction which accesses the TOD clock, CPU timer, or clock comparator produces incorrect results. Depending on the model, the TOD programmable register, CPU timer, or clock comparator may be validated by the interruption which reports the TOD programmable register, CPU timer, or clock comparator as invalid.

Timing-facility damage is a repressible condition. It is masked by the external-damage subclass-mask bit, which is in bit position 38 of control register 14.

Timing-facility-damage conditions for the CPU timer and the clock comparator are not recognized on most models when these facilities are not in use. The facilities are considered not in use when the CPU is disabled for the corresponding external interruptions (PSW bit 7, or the subclass-mask bits, bits 52 and 53 of control register 0, are zeros), and when the corresponding set and store instructions are not executed. Timing-facility-damage conditions that are already pending remain pending, however, when the CPU is disabled for the corresponding external interruption.

Timing-facility-damage conditions due to damage to the TOD clock are always recognized.

With TOD-clock steering, damage to the TOD clock is considered to be of such severity that it is undesirable to continue operation. When the TOD-clock

steering facility is installed, and damage has occurred to the TOD-clock-steering registers or the TOD clock and the damage is limited to a single CPU, then that CPU enters the check-stop state. If the TOD clock is in the not-operational state or error state, or when damage has occurred to the TOD-clock-steering registers or the TOD clock, and the damage affects all CPUs, then a system check stop occurs.

### External Damage

Bit 5 (ED), when one, indicates that damage has occurred during operations not directly associated with processing the current instruction.

When bit 5, external damage, is one and bit 26, external-damage-code validity, is also one, the external-damage code has been stored to indicate, in more detail, the cause of the external-damage machine-check interruption. When the external damage cannot be isolated to one or more of the conditions as defined in the external-damage code, or when the detailed indication for the condition is not implemented by the model, external damage is indicated with bit 26 set to zero. The presence and extent of reporting external damage depend on the model.

External damage is a repressible condition. It is masked by the external-damage subclass-mask bit, which is in bit position 38 of control register 14.

### Degradation

Bit 7 (DG), when one, indicates that continuous degradation of system performance, more serious than that indicated by system recovery, has occurred. Degradation may be reported when system-recovery conditions exceed a machine-preestablished threshold or when unit deletion has occurred. The presence and extent of the degradation-report capability depend on the model.

Degradation is a repressible condition. It is masked by the degradation subclass-mask bit, which is in bit position 37 of control register 14.

### Warning

Bit 8 (W), when one, indicates that damage is imminent in some part of the system (for example, that power is about to fail, or that a loss of cooling is occurring). Whether warning conditions are recognized depends on the model.

If the condition responsible for the imminent damage is removed before the interruption request is honored (for example, if power is restored), the request does not remain pending, and no interruption occurs. Conversely, the request is not cleared by the interruption, and, if the condition persists, more than one interruption may result from the same condition.

Warning is a repressible condition. It is masked by the warning subclass-mask bit, which is in bit position 39 of control register 14.

### Channel Report Pending

Bit 9 (CP), when one, indicates that a channel report, consisting of one or more channel-report words, has been made pending, and the contents of the channel-report words describe, in further detail, the effect of the malfunction and the results of analysis or the action performed. A channel report becomes pending when one of the following conditions has occurred:

1. Channel-subsystem recovery has been completed. The channel-subsystem recovery may have been initiated with no prior notice to the program or may have been a result of a condition previously reported to the program.
2. The function specified by RESET CHANNEL PATH has been completed.

A channel report may also become pending under other conditions.

The channel-report words which make up the channel report may be cleared, one at a time, by execution of the instruction STORE CHANNEL REPORT WORD, which is described in "I/O Instructions" on page 14-1.

Bit 9 is meaningless when channel-subsystem damage is reported.

Channel report pending is a floating repressible condition. It is masked by the channel-report-pending subclass-mask bit, which is in bit position 35 of control register 14.

### Service-Processor Damage

Bit 10 (SP), when one, indicates that damage has occurred to the service processor. Service-processor damage may be made pending at all CPUs in the configuration, or it may be detected independently by

each CPU. The presence and extent of reporting service-processor damage depend on the model.

Service-processor damage is a repressible condition and has no subclass-mask bit.

### Channel-Subsystem Damage

Bit 11 (CK), when one, indicates that an error or malfunction has occurred in the channel subsystem, or that the channel subsystem is in the check-stop state. The channel subsystem enters the check-stop state when a malfunction occurs which is so severe that the channel subsystem cannot continue, or if power is lost in the channel subsystem.

Channel-subsystem damage is a floating repressible condition and has no subclass-mask bit.

### Subclass Modifiers

Bits 14 (B), 34 (DA), and 44 (AP) of the machine-check-interruption code act as modifiers to the subclass bits.

#### Backed Up

Bit 14 (B), when one, indicates that the point of interruption is at a checkpoint before the point of error. This bit is meaningful only when the instruction-processing-damage bit, bit 1, is also set to one. The presence and extent of the capability to indicate a backed-up condition depend on the model.

#### Delayed Access Exception

Bit 34 (DA), when one, indicates that an access exception was detected during a storage access using DAT when no such exception was detected by an earlier test for access exceptions.

Bit 34 is a modifier to instruction-processing damage (bit 1) and is meaningful only when bit 1 of the machine-check-interruption code is one. When bit 1 is zero, bit 34 has no meaning. The presence and extent of reporting delayed access exception depend on the model.

**Programming Note:** The occurrence of a delayed access exception normally indicates that the program is using an improper procedure to update the DAT tables.

#### Ancillary Report

Bit 44 (AP), when one, indicates that a malfunction of a system component has occurred which has been recognized previously or which has affected the activities of multiple system elements such as CPUs and subchannels. When the malfunction affects the activities of multiple elements, an ancillary-report condition is recognized for all of the affected elements except one. This bit, when zero, indicates that this malfunction of a system component has not been recognized previously. This bit is meaningful for all conditions indicated by either the machine-check-interruption code or the external-damage code.

Depending on the model, recognition of an ancillary-report condition may not be provided, or it may not be provided for all system malfunctions. When ancillary-report recognition is not provided, bit 44 is set to zero.

### Synchronous Machine-Check-Interruption Conditions

The instruction-processing damage and backed-up bits, bits 1 and 14 of the machine-check-interruption code, identify, in combination, two conditions.

Bit 1	Bit 14	Name of Condition
1	0	Processing damage
1	1	Processing backup

#### Processing Backup

The processing-backup condition indicates that the point of interruption is prior to the point, or points, of error. This is a nullifying exigent condition. When all of the other CPU-related-damage subclasses and modifiers of the machine-check-interruption code are zero, and certain validity bits associated with CPU status are indicated as valid, then the machine has successfully returned to a checkpoint prior to the malfunction, and no damage has yet occurred to the CPU.

The subclass bits which must be zero for no damage to have occurred are as follows:

MCIC	Bit	Name
	0	System damage
	4	Timing-facility damage

The delayed-access-exception subclass-modifier bit, MCIC bit 34, must be zero for no damage to have occurred.

The validity bits in the machine-check-interruption code which must be one for no damage to have occurred are as follows:

#### MCIC

Bit	Name
20	PSW MWP bits
21	PSW mask and key
22	PSW program mask and condition code
23	PSW instruction address
27	Floating-point registers
28	General registers
29	Control registers
31	Storage logical validity (result fields within current checkpoint interval)
33	Access registers
42	TOD programmable register
43	Floating-point-control register
46	CPU timer
47	Clock comparator

**Programming Note:** The processing-backup condition is reported rather than system recovery to indicate that a malfunction or failure stands in the way of continued operation of the CPU. The malfunction has not been circumvented, and damage would have occurred if instruction processing had continued.

#### Processing Damage

The processing-damage condition indicates that damage has occurred to the instruction processing of the CPU. The point of interruption is a point beyond some or all of the points of damage. Processing damage is a terminating exigent condition; therefore, the contents of result fields may be unpredictable and still indicated as valid.

Processing damage may include malfunctions in program-event recording, monitor call, tracing, access-register translation, and dynamic address translation. Processing damage causes any supervisor-call-interruption condition and program-interruption condition to be discarded. However, the contents of the old PSW and interruption-code locations for these interruptions may be set to unpredictable values.

## Storage Errors

Bits 16-18 of the machine-check-interruption code are used to indicate an invalid CBC or a near-valid CBC detected in main storage or an invalid CBC in a storage key. Bit 19, storage degradation, may be indicated concurrently with bit 17. The failing-storage-address field, when indicated as valid, identifies a location within the storage checking block containing the error, or, for storage-key error uncorrected, within the block associated with the storage key. Bit 32, indirect storage error, may be set to one to indicate that the location designated by the failing-storage address is not the original source of the error.

The storage-error-uncorrected and storage-key-error-uncorrected bits do not in themselves indicate the occurrence of damage because the error detected may not have affected a result. The portion of the configuration affected by an invalid CBC is indicated in the subclass field of the machine-check-interruption code.

Storage errors detected for a channel program, when indicated as I/O-error conditions, may also be reported as system recovery. CBC errors that occur in storage or in the storage key and that are detected on prefetched or unused data for a CPU program may or may not be reported, depending on the model.

#### Storage Error Uncorrected

Bit 16 (SE), when one, indicates that a checking block in main storage contained invalid CBC and that the information could not be corrected. The contents of the checking block in main storage have not been changed. The location reported may have been accessed or prefetched for this CPU or another CPU or a channel program, or it may have been accessed as the result of a model-dependent storage access.

#### Storage Error Corrected

Bit 17 (SC), when one, indicates that a checking block in main storage contained near-valid CBC and that the information has been corrected before being used. Depending on the model, the contents of the checking block in main storage may or may not have been restored to valid CBC. The location reported may have been accessed or prefetched for this CPU or for another CPU or for a channel program, or it may have been accessed as the result of a model-dependent storage access. The presence and extent of the storage-error-correction capability depend on

the model. This indication may or may not be accompanied by an indication of storage degradation, bit 19 (DS).

### **Storage-Key Error Uncorrected**

Bit 18 (KE), when one, indicates that a storage key contained invalid CBC and that the information could not be corrected. The contents of the checking block in the storage key have not been changed. The storage key may have been accessed or prefetched for this CPU or for another CPU or for a channel program, or it may have been accessed as the result of a model-dependent storage access.

### **Storage Degradation**

Bit 19 (DS), when one, indicates that degradation of the recovery characteristics has occurred for the 4K-byte block reported by the failing-storage address.

Storage degradation indicates that although the associated storage error has been corrected, there are solid failures associated with the storage block (or with its associated key) that cause the correction process to take a substantial amount of time, and that if an additional error occurs in the block, the error may not be correctable or may go undetected. Thus, this bit indicates that use of the indicated block of storage should be avoided, if possible.

The indication of storage degradation has meaning only when failing-storage-address validity, MCIC bit 24, is also one. The presence and extent of reporting storage degradation depend on the model.

Because storage degradation is normally reported with system recovery, the recovery subclass mask, bit 36 of control register 14, should be set to one in order for storage degradation to be indicated.

### **Indirect Storage Error**

Bit 32 (IE), when one, indicates that the physical main-storage location identified by the failing-storage address is not the original source of the error. Instead, the error originated in another level of the storage hierarchy and has been propagated to the current physical-storage portion of the storage hierarchy. Bit 32 is meaningful only when bit 16 or 18 (storage error uncorrected or storage-key error uncorrected) of the machine-check-interruption code is one. When bits 16 and 18 are both zeros, bit 32 has no meaning.

For errors originating outside the storage hierarchy, the attempt to store is rejected, and the appropriate error indication is presented. When an error is detected during implicit movement of information inside the storage hierarchy, the action is not rejected and reported in this manner because the movement may be asynchronous and may be initiated as the result of an attempt to access completely unrelated information. Instead, errors in the contents of the source during implicit moving of information from one portion of the storage hierarchy to another may be preserved in the target area by placing a special invalid CBC in the checking block associated with the target location. These propagated errors, when detected later, are reported as indirect storage errors. The original source of such an error may have been in a cache associated with an I/O processor or a CPU, or the error may have been the result of a data-path failure in transmitting data from one portion of the storage hierarchy to another. Additionally, a propagated error may be generated during the movement of data from one physical portion of storage to another as the result of a storage-reconfiguration action.

The presence and extent of reporting indirect storage error depend on the model.

**Programming Note:** See the programming notes under TEST BLOCK in Chapter 10, “Control Instructions” for the action which should be taken after storage errors are reported.

## **Machine-Check Interruption-Code Validity Bits**

Bits 20-24, 26-29, 31, 33, 42, 43, 46, and 47 of the machine-check-interruption code are validity bits. Each bit indicates the validity of a particular field in storage. With the exception of the storage-logical-validity bit (bit 31), each bit is associated with a field stored during the machine-check interruption. When a validity bit is one, it indicates that the saved value placed in the corresponding storage field is valid with respect to the indicated point of interruption and that no error was detected when the data was stored.

When a validity bit is zero, one or more of the following conditions may have occurred: the original information was incorrect, the original information had invalid CBC, additional malfunctions were detected while storing the information, or none or only part of

the information was stored. Even though the information is unpredictable, the machine attempts, when possible, to place valid CBC in the storage field and thus reduce the possibility of additional machine checks being caused.

The validity bits for the floating-point registers, general registers, control registers, access registers, TOD programmable register, floating-point control register, CPU timer, and clock comparator indicate the validity of the saved value placed in the corresponding save area. The information in these registers after the machine-check interruption is not necessarily correct even when the correct value has been placed in the save area and the validity bit set to one. The use of the registers and the operation of the facility associated with the control registers, floating-point control register, TOD programmable register, CPU timer, and clock comparator are unpredictable until these registers are validated. (See "Invalid CBC in Registers" on page 8.)

### **PSW-MWP Validity**

Bit 20 (WP), when one, indicates that bits 12-15 of the machine-check old PSW are correct.

### **PSW Mask and Key Validity**

Bit 21 (MS), when one, indicates that the system mask, PSW key, and miscellaneous bits of the machine-check old PSW are correct. Specifically, this bit covers bits 0-11, 16, 17, 24-30, and 33-63 of the PSW.

### **PSW Program-Mask and Condition-Code Validity**

Bit 22 (PM), when one, indicates that the program mask and condition code of the machine-check old PSW are correct.

### **PSW-Instruction-Address Validity**

Bit 23 (IA), when one, indicates that the addressing-mode and instruction-address bits, bits 31, 32, and 64-127, of the machine-check old PSW are correct.

### **Failing-Storage-Address Validity**

Bit 24 (FA), when one, indicates that a correct failing-storage address has been stored at real location 248-255 after a storage-error-uncorrected, storage-key-error-uncorrected, or storage-error-corrected condition has occurred. The presence and extent of the capability to identify the failing-storage location depend on the model. When no such errors are

reported, that is, bits 16-18 of the machine-check-interruption code are zeros, the failing-storage address is meaningless, even though it may be indicated as valid.

### **External-Damage-Code Validity**

Bit 26 (EC), when one, and provided that bit 5, external damage, is also one, indicates that a valid external-damage code has been stored in the word at real location 244. When bit 5 is zero, bit 26 has no meaning.

### **Floating-Point-Register Validity**

Bit 27 (FP), when one, indicates that the contents of the floating-point-register save area at real locations 4608-4735 reflect the correct state of the floating-point registers at the point of interruption.

### **General-Register Validity**

Bit 28 (GR), when one, indicates that the contents of the general-register save area at real locations 4736-4863 reflect the correct state of the general registers at the point of interruption.

### **Control-Register Validity**

Bit 29 (CR), when one, indicates that the contents of the control-register save area at real locations 4992-5119 reflect the correct state of the control registers at the point of interruption.

### **Storage Logical Validity**

Bit 31 (ST), when one, indicates that the storage locations, the contents of which are modified by the instructions being executed, contain the correct information relative to the point of interruption. That is, all stores before the point of interruption are completed, and all stores, if any, after the point of interruption are suppressed. When a store before the point of interruption is suppressed because of an invalid CBC, the storage-logical-validity bit may be indicated as one, provided that the invalid CBC has been preserved as invalid.

When instruction-processing damage is indicated but processing backup is not indicated, the storage-logical-validity bit has no meaning.

Storage logical validity reflects only the instruction-processing activity and does not reflect errors in the state of storage as the result of either I/O operations or the storing of the old PSW and other interruption information.

## **Access-Register Validity**

Bit 33 (AR), when one, indicates that the contents of the access-register save area at real locations 4928-4991 reflect the correct state of the access registers at the point of interruption.

## **TOD-Programmable-Register Validity**

Bit 42 (PR), when one, indicates that the contents of the TOD-programmable-register save area at real locations 4900-4903 reflect the correct state of the TOD programmable register at the point of interruption.

## **Floating-Point-Control-Register Validity**

Bit 43 (FC), when one, indicates that the contents of the floating-point-control-register save area at real locations 4892-4895 reflect the correct state of the floating-point-control register at the point of interruption.

## **CPU-Timer Validity**

Bit 46 (CT), when one, indicates that the CPU timer is not in error and that the contents of the CPU-timer save area at real locations 4904-4911 reflect the correct state of the CPU timer at the time the interruption occurred.

## **Clock-Comparator Validity**

Bit 47 (CC), when one, indicates that the clock comparator is not in error, that the contents of the clock-comparator save area at real locations 4913-4919 reflect the correct state of the clock comparator at the time the interruption occurred, and that zeros have been stored at real location 4912.

**Programming Note:** The validity bits must be used in conjunction with the subclass bits and the backed-up bit in order to determine the extent of the damage caused by a machine-check condition. No damage has occurred to the system when all of the following are true:

- The four PSW-validity bits, the six register-validity bits, the two timing-facility-validity bits, and the storage-logical-validity bit are all ones.
- Subclass bits 0, 4, 5, 10, and 11 are zeros.
- The instruction-processing-damage bit is zero or, if one, the backed-up bit is also one.
- The delayed-access-exception bit is zero.

---

## **Machine-Check Extended Interruption Information**

As part of the machine-check interruption, in some cases, extended interruption information is placed in fixed areas assigned in storage. The contents of registers associated with the CPU are placed in register-save areas. For external damage, additional information is provided for some models by storing an external-damage code. When storage error uncorrected, storage error corrected, or storage-key error uncorrected is indicated, the failing-storage address is saved.

Each of these fields has associated with it a validity bit in the machine-check-interruption code. If, for any reason, the machine cannot store the proper information in the field, the associated validity bit is set to zero.

## **Register-Save Areas**

As part of the machine-check interruption, the current contents of the CPU registers, except for the prefix register and the TOD clock, are stored in eight register-save areas assigned in storage. Each of these areas has associated with it a validity bit in the machine-check-interruption code. If, for any reason, the machine cannot store the proper information in the field, the associated validity bit is set to zero.

The following are the eight sets of registers and the real locations in storage where their contents are saved during a machine-check interruption.

Locations	Registers
4608-4735	Floating-point registers 0-15
4736-4863	General registers 0-15
4892-4895	Floating-point-control register
4900-4903	TOD programmable register
4904-4911	CPU timer
4913-4919	Clock comparator
4928-4991	Access registers 0-15
4992-5119	Control registers 0-15

## **External-Damage Code**

The word at real location 244 is the external-damage code. This field, when implemented and indicated as valid, describes the cause of external damage. The

field is valid only when the external-damage bit and the external-damage-code-validity bit (bits 5 and 26 in the machine-check-interruption code) are both ones. The presence and extent of reporting an external-damage code depend on the model.

The external-damage code has the following format:

**ETR Sync Check (SC):** Bit 19, when one, indicates that bits 32 through the rightmost incremented bit of a running clock are not in synchronism with the same bits of the ETR.

If the condition happens more than once before the interruption occurs, the condition is generated only once. The condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

**STP Sync Check (SS):** Bit 24, when one, indicates that an STP-sync-check has occurred. The STP-sync-check condition is generated when the configuration is in the STP-timing mode and the timing state changes from the synchronized state to the unsynchronized or stopped state.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

***Island Condition (IC):*** Bit 25, when one, indicates that an island condition has been detected. The island condition is generated when an attached server attempts to communicate over an STP link and both of the following conditions are detected:

- The servers have matching CTN IDs, and
  - Both servers have valid stratum-1-configurations and the configurations do not match.

The island condition indicates that two separate CTNs may be operating with the same CTN ID.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

**CTN Configuration Change (CC):** Bit 26, when one, indicates that a CTN-configuration-change has

occurred in the CTN. The conditions that cause the CTN-configuration-change condition to be generated include the following:

- A new node with a matching CTN ID has attached to this node.
  - An attached node that had a matching CTN ID is no longer attached to this node
  - The CTN ID for this node has changed.
  - The stratum level of this node has changed, or a change in the stratum-1 or alternate-stratum-1 for the network has changed.
  - STP active or maximum version number has changed.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

**STP Clock Source Error (CS):** Bit 27, when one, indicates that an STP-clock-source error has occurred. The STP-clock-source condition is generated when the configuration is in the STP-timing mode and the STP-clock-source state changes from the usable state to the not-usable state.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

**Reserved:** Bits 0-7, 10-16, 21-23, and 28-31 are reserved for future expansion and are always set to zero.

# Failing-Storage Address

When storage error uncorrected, storage error corrected, or storage-key error uncorrected is indicated in the machine-check-interruption code, the associated address, called the failing-storage address, is stored at real locations 248-255. The field is valid only if the failing-storage-address validity bit, bit 24 of the machine-check-interruption code, is one.

In the case of storage errors, the failing-storage address may designate any byte within the checking block. For storage-key error uncorrected, the failing-storage address may designate any address within the block of storage associated with the storage key that is in error. When an error is detected in more

than one location before the interruption, the failing-storage address may designate any of the failing locations. The address stored is an absolute address; that is, the value stored is the address that is used to reference storage after dynamic address translation and prefixing have been applied.

---

## Handling of Machine-Check Conditions

### Floating Interruption Conditions

An interruption condition which is made available to any CPU in a multiprocessing configuration is called a floating interruption condition. The first CPU that accepts the interruption clears the interruption condition, and it is no longer available to any other CPU in the configuration.

Floating interruption conditions include service-signal external-interruption and I/O-interruption conditions. Two machine-check-interruption conditions, channel report pending and channel-subsystem damage, are floating interruption conditions. Depending on the model, some machine-check-interruption conditions associated with system recovery and warning may also be floating interruption conditions.

A floating interruption is presented to the first CPU in the configuration which is enabled for the interruption condition and can accept the interruption. A CPU cannot accept the interruption when the CPU is in the check-stop state, has an invalid prefix, is performing an unending string of interruptions due to a PSW-format error of the type that is recognized early, or is in the stopped state. However, a CPU with the rate control set to instruction step can accept the interruption when the start key is activated.

**Programming Note:** When a CPU enters the check-stop state in a multiprocessing configuration, the program on another CPU can determine whether a floating interruption may have been reported to the failing CPU and then lost. This can be accomplished if the interruption program places zeros in the real storage locations containing old PSWs and interruption codes after the interruption has been handled (or has been moved into another area for later processing). After a CPU enters the check-stop state, the program on another CPU can inspect the old-PSW and interruption-code locations of the failing CPU. A nonzero

value in an old PSW or interruption code indicates that the CPU has been interrupted but the program did not complete the handling of the interruption.

### Floating Machine-Check-Interruption Conditions

Floating machine-check-interruption conditions are reset only by the manually initiated resets through the operator facilities. When a machine check occurs which prohibits completion of a floating machine-check interruption, the interruption condition is no longer considered a floating interruption condition, and system damage is indicated.

### Floating I/O Interruptions

The detection of a machine malfunction by the channel subsystem, while in the process of presenting an I/O-interruption request for a floating I/O interruption, may be reported as channel report pending or as channel-subsystem damage. Detection of a machine malfunction by a CPU, while in the process of accepting a floating I/O interruption, is reported as system damage.

---

## Machine-Check Masking

All machine-check interruptions are under control of the machine-check mask, PSW bit 13. In addition, some machine-check conditions are controlled by subclass masks in control register 14.

The exigent machine-check conditions (system damage and instruction-processing damage) are controlled only by the machine-check mask, PSW bit 13. When PSW bit 13 is one, an exigent condition causes a machine-check interruption. When PSW bit 13 is zero, the occurrence of an exigent machine-check condition causes the CPU to enter the check-stop state.

The repressible machine-check conditions, except channel-subsystem damage and service-processor damage, are controlled both by the machine-check mask, PSW bit 13, and by five subclass-mask bits in control register 14. If PSW bit 13 is one and one of the subclass-mask bits is one, the associated condition initiates a machine-check interruption. If a subclass-mask bit is zero, the associated condition does not initiate an interruption but is held pending. However, when a machine-check interruption is initiated because of a condition for which the CPU is enabled,

those conditions for which the CPU is not enabled may be presented along with the condition which initiates the interruption. All conditions presented are then cleared.

Control register 14 contains mask bits that specify whether certain conditions can cause machine-check interruptions. It has the following format:

...		C	R	D	E	W		...
32		R	M	M	M	M		35 36 37 38 39 40

Bits 35-39 of control register 14 are the subclass masks for repressible machine-check conditions. In addition, bit 32 of control register 14 is initialized to one but is otherwise ignored by the machine.

**Programming Note:** The program should avoid, whenever possible, operating with PSW bit 13, the machine-check mask, set to zero, since any exigent machine-check condition which is recognized during this situation will cause the CPU to enter the check-stop state. In particular, the program should avoid executing I/O instructions or allowing I/O interruptions with PSW bit 13 zero.

### Channel-Report-Pending Subclass Mask

Bit 35 (CM) of control register 14 controls channel-report-pending interruption conditions. This bit is initialized to zero.

### Recovery Subclass Mask

Bit 36 (RM) of control register 14 controls system-recovery interruption conditions. This bit is initialized to zero.

### Degradation Subclass Mask

Bit 37 (DM) of control register 14 controls degradation interruption conditions. This bit is initialized to zero.

### External-Damage Subclass Mask

Bit 38 (EM) of control register 14 controls timing-facility-damage and external-damage interruption conditions. This bit is initialized to one.

### Warning Subclass Mask

Bit 39 (WM) of control register 14 controls warning interruption conditions. This bit is initialized to zero.

---

### Machine-Check Logout

As part of the machine-check interruption, some models may place model-dependent information in the fixed-logout area. This area is 16 bytes in length and starts at real location 4864.

## Summary of Machine-Check Masking

A summary of machine-check masking is given in Figure 11-4 and Figure 11-5.

Machine-Check Condition		Sub-Class Mask	Action when CPU Disabled for Subclass
MCIC Bit	Subclass		
0	System damage	-	Check stop
1	Instruction-processing damage	-	Check stop
2	System recovery	RM	Y
4	Timing-facility damage	EM	P
5	External damage	EM	P
7	Degradation	DM	P
8	Warning	WM	P
9	Channel report pending	CM	P
10	Service-processor damage	-	P
11	Channel-subsystem damage	-	P

**Explanation:**

- The condition does not have a subclass mask.
- P Indication is held pending.
- Y Indication may be held pending or may be discarded.
- CM Channel-report-pending subclass mask (bit 35 of CR14).
- DM Degradation subclass mask (bit 37 of CR14).
- EM External-damage subclass mask (bit 38 of CR14).
- RM Recovery subclass mask (bit 36 of CR14).
- WM Warning subclass mask (bit 39 of CR14).

Figure 11-4. Machine-Check-Condition Masking

Bit Description	Control Register 14 Bit Position	State of Bit on Initial CPU Reset
Channel-report-pending subclass mask	35	0
Recovery subclass mask	36	0
Degradation subclass mask	37	0
External-damage subclass mask	38	1
Warning subclass mask	39	0

## Manual Operation

The operator facilities provide functions for the manual operation and control of the machine. The functions include operator-to-machine communication, indication of machine status, control over the setting of the TOD clock, initial program loading, resets, and other manual controls for operator intervention in normal machine operation. A model may not implement all of the operator facilities described in this chapter.

A model may provide additional operator facilities which are not described in this chapter. Examples are the means to indicate specific error conditions in the equipment, to change equipment configurations, and to facilitate maintenance. Furthermore, controls covered in this chapter may have additional settings which are not described here. Such additional facilities and settings may be described in the appropriate System Library publication.

Most models provide, in association with the operator facilities, a console device which may be used as an I/O device for operator communication with the program; this console device may also be used to implement some or all of the facilities described in this chapter.

The operator facilities may be implemented on different models in various technologies and configurations. On some models, more than one set of physical representations of some keys, controls, and

indicators may be provided, such as on multiple local or remote operating stations, which may be effective concurrently.

A machine malfunction that prevents a manual operation from being performed correctly, as defined for that operation, may cause the CPU to enter the check-stop state or give some other indication to the operator that the operation has failed. Alternatively, a machine malfunction may cause a machine-check-interruption condition to be recognized.

## Basic Operator Facilities

### Address-Compare Controls

The address-compare controls provide a way to stop the CPU when a preset address matches the address used in a specified type of main-storage reference.

One of the address-compare controls is used to set up the address to be compared with the storage address.

Another control provides at least two positions to specify the action, if any, to be taken when the address match occurs:

1. The normal position disables the address-compare operation.

2. The stop position causes the CPU to enter the stopped state on an address match. When the control is in this setting, the test indicator is on. Depending on the model and the type of reference, pending I/O, external, and machine-check interruptions may or may not be taken before entering the stopped state.

A third control may specify the type of storage reference for which the address comparison is to be made. A model may provide one or more of the following positions, as well as others:

1. The any position causes the address comparison to be performed on all storage references.
2. The data-store position causes address comparison to be performed when storage is addressed to store data.
3. The I/O position causes address comparison to be performed when storage is addressed by the channel subsystem to transfer data or to fetch a channel-command or indirect-data-address word. Whether references to the measurement block, interruption-response block, channel-path-status word, channel-report word, subchannel-status word, subchannel-information block, and operation-request block cause a match to be indicated depends on the model.
4. The instruction-address position causes address comparison to be performed when storage is addressed to fetch an instruction. The rightmost bit of the address setting may or may not be ignored. The match is indicated only when the first byte of the instruction is fetched from the selected location (which includes fetching the target instruction of an execute-type instruction).

Depending on the model and the type of reference, address comparison may be performed on virtual, real, or absolute addresses, and it may be possible to specify the type of address.

In a multiprocessing configuration, it depends on the model whether the address setting applies to one or all CPUs in the configuration and whether an address match causes one or all CPUs in the configuration to stop.

## Alter-and-Display Controls

The operator facilities provide controls and procedures to permit the operator to alter and display the contents of locations in storage, the storage keys, the general, floating-point, floating-point-control, access, and control registers, the prefix, and the PSW.

Before alter-and-display operations may be performed, the CPU must first be placed in the stopped state. During alter-and-display operations, the manual indicator may be turned off temporarily, and the start and restart keys may be inoperative.

Addresses used to select storage locations for alter-and-display operations are real addresses. The capability of specifying logical, virtual, or absolute addresses may also be provided.

## Architectural-Mode Indicator

The architectural-mode indicator shows the architectural mode of operation (the ESA/390 mode, z/Architecture mode, or some other mode) selected by the last architectural-mode-selection operation and by the last SIGNAL PROCESSOR set-architecture order or the last reset that determined the mode.

## Architectural-Mode-Selection Controls

The architectural-mode-selection controls provide for the selection of either the ESA/390 architectural mode of operation or, possibly, some other architectural mode of operation. (The z/Architecture mode is selected from the ESA/390 mode by the SIGNAL PROCESSOR set-architecture order.) Depending on the model, the architectural-mode selection may be provided as part of the IML operation or may be a separate operation.

As part of the architectural-mode-selection process, all CPUs and the associated channel-subsystem components in a particular configuration are placed in the same architectural mode.

## Check-Stop Indicator

The check-stop indicator is on when the CPU is in the check-stop state. Reset operations normally

cause the CPU to leave the check-stop state and thus turn off the indicator. The manual indicator may also be on in the check-stop state.

## IML Controls

The IML controls provided with some models perform initial machine loading (IML), which is the loading of licensed internal code into the machine. The IML operation, when provided, may be used to select the ESA/390 mode or, possibly, some other mode of operation.

When the IML operation is completed, the state of the affected CPUs, channel subsystem, main storage, and operator facilities is the same as if a power-on reset had been performed, except that the value and state of the TOD clock are not changed. The contents of expanded storage may have been cleared to zeros with valid checking-block code or may have remained unchanged, depending on the model.

The IML controls are effective while the power is on.

## Interrupt Key

When the interrupt key is activated, an external-interruption condition indicating the interrupt key is generated. (See “Interrupt Key” on page 6-11.)

The interrupt key is effective when the CPU is in the operating or stopped state. It depends on the model whether the interrupt key is effective when the CPU is in the load state.

## Load Indicator

The load indicator is on during CCW-type initial program loading, indicating that the CPU is in the load state. The indicator goes on for a particular CPU when the load-clear or load-normal key is activated for that CPU and the corresponding operation is started. It goes off after the new PSW is loaded successfully. For details, see “Initial Program Loading” on page 4-55.)

## Load-Clear Key

Activating the load-clear key causes a reset operation to be performed and CCW-type initial program loading to be started by using the I/O device designated by the load-unit-address controls. Clear reset is performed on the configuration. For details, see “Resets” on page 4-49 and “Initial Program Loading” on page 4-55.

The load-clear key is effective when the CPU is in the operating, stopped, load, or check-stop state.

## Load-Clear-List-Directed Key

Activating the load-clear-list-directed key causes a reset operation to be performed and list-directed initial program loading to be started using the I/O device designated by the list-directed IPL parameters. Clear reset is performed on the configuration. For details, see “Resets” on page 4-49 and “List-Directed IPL” on page 17-19.

The load-clear-list-directed key is effective when the CPU is in the operating, stopped, load, or check-stop state.

## Load-Normal Key

Activating the load-normal key causes a reset operation to be performed and CCW-type initial program loading to be started by using the I/O device designated by the load-unit-address controls. Initial CPU reset is performed on the CPU for which the load-normal key was activated, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration. For details, see “Resets” on page 4-49 and “Initial Program Loading” on page 4-55.

The load-normal key is effective when the CPU is in the operating, stopped, load, or check-stop state.

## Load-with-Dump Key

Activating the load-with-dump key causes a reset operation to be performed and list-directed initial program loading to be started by using the I/O devices designated by the list-directed IPL parameters. A store-status operation followed by an initial CPU reset is performed on the CPU for which the load-

with-dump key was activated, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration. For details, see “Resets” on page 4-49 and “List-Directed IPL” on page 17-19.

The load-with-dump key is effective when the CPU is in the operating, stopped, load, or check-stop state.

## Load-Unit-Address Controls

The load-unit-address controls specify four hexadecimal digits that provide the device number used for CCW-type initial program loading. For details, see “Initial Program Loading” on page 4-55.

## Manual Indicator

The manual indicator is on when the CPU is in the stopped state. Some functions and several manual controls are effective only when the CPU is in the stopped state.

## Power Controls

The power controls are used to turn the power on and off.

The CPUs, storage, channel subsystem, operator facilities, and I/O devices may all have their power turned on and off by common controls, or they may have separate power controls. When a particular unit has its power turned on, that unit is reset. The sequence is performed so that no instructions or I/O operations are performed until explicitly specified. The controls may also permit power to be turned on in stages, but the machine does not become operational until power on is complete.

When the power is completely turned on, an IML operation is performed on models which have an IML function. A power-on reset is then initiated (see “Resets” on page 4-49). It depends on the model whether the architectural mode of operation can be selected when the power is turned on, or whether the mode-selection controls have to be used to change the mode after the power is on.

## Rate Control

A model may provide the rate control, the setting of which determines the effect of the start function and the manner in which instructions are executed.

When the rate control is provided, it has at least two positions. The normal position is the process position. Another position is the instruction-step position. When the rate control is set to the process position and the start function is performed, the CPU starts operating at normal speed. When the rate control is set to the instruction-step position and the wait-state bit is zero, one instruction or, for interruptible instructions, one unit of operation is executed, and all pending allowed interruptions are taken before the CPU returns to the stopped state. When the rate control is set to the instruction-step position and the wait-state bit is one, no instruction is executed, but all pending allowed interruptions are taken before the CPU returns to the stopped state. For details, see “Stopped, Operating, Load, and Check-Stop States” on page 4-1.

The test indicator is on while the rate control is not set to the process position.

If the setting of the rate control is changed while the CPU is in the operating or load state, the results are unpredictable.

When the rate control is not provided, the CPU operates as though the rate control was in the process position, and instruction stepping is not available.

## Restart Key

Activating the restart key initiates a restart interruption. (See “Restart Interruption” on page 6-49.)

The restart key is effective when the CPU is in the operating or stopped state. The key is not effective when the CPU is in the check-stop state. It depends on the model whether the restart key is effective when any CPU in the configuration is in the load state.

The effect is unpredictable when the restart key is activated while any CPU in the configuration is in the load state. In particular, if the CPU performs a restart interruption and enters the operating state while another CPU is in the load state, operations such as

I/O instructions, the SIGNAL PROCESSOR instruction, and the INVALIDATE PAGE TABLE ENTRY instruction may not operate according to the definitions given in this publication

## Start Key

Activating the start key causes the CPU to perform the start function. (See “Stopped, Operating, Load, and Check-Stop States” on page 4-1.)

The start key is effective only when the CPU is in the stopped state. The effect is unpredictable when the stopped state has been entered by a reset.

## Stop Key

Activating the stop key causes the CPU to perform the stop function. (See “Stopped, Operating, Load, and Check-Stop States” on page 4-1.)

The stop key is effective only when the CPU is in the operating state.

**Operation Note:** Activating the stop key has no effect when:

- An unending string of certain program or external interruptions occurs.
- The prefix register contains an invalid address.
- The CPU is in the load or check-stop state.

## Store-Status Key

Activating the store-status key initiates a store-status operation. (See “Store Status” on page 4-55.)

The store-status key is effective only when the CPU is in the stopped state.

**Operation Note:** The store-status operation may be used in conjunction with a standalone dump program for the analysis of major program malfunctions. For such an operation, the following sequence would be called for:

- Activation of the stop or system-reset-normal key
- Activation of the store-status key
- Activation of the load-normal key to enter a stand-alone dump program

The system-reset-normal key must be activated in step 1 when (1) the stop key is not effective because a continuous string of interruptions is occurring, (2) the prefix register contains an invalid address, or (3) the CPU is in the check-stop state.

## System-Reset-Clear Key

Activating the system-reset-clear key causes a clear-reset operation to be performed on the configuration. For details, see “Resets” on page 4-49.

The system-reset-clear key is effective when the CPU is in the operating, stopped, load, or check-stop state.

## System-Reset-Normal Key

Activating the system-reset-normal key causes a CPU-reset operation and a subsystem-reset operation to be performed. In a multiprocessing configuration, a CPU reset is propagated to all CPUs in the configuration. For details, see the section “Resets” in Chapter 4, “Control.”

The system-reset-normal key is effective when the CPU is in the operating, stopped, load, or check-stop state.

## Test Indicator

The test indicator is on when a manual control for operation or maintenance is in an abnormal position that can affect the normal operation of a program.

Setting the address-compare controls to the stop position or setting the rate control to the instruction-step position turns on the test indicator.

The test indicator may be on when one or more diagnostic functions under the control of DIAGNOSE are activated, or when other abnormal conditions occur.

The abnormal setting of a manual control causes the test indicator of the affected CPU to be turned on; however, in a multiprocessing configuration, the operation of other CPUs may be affected even though their test indicators are not turned on.

**Operation Note:** If a manual control is left in a setting intended for maintenance purposes, such an

abnormal setting may, among other things, result in false machine-check indications or cause actual machine malfunctions to be ignored. It may also alter other aspects of machine operation, including instruction execution, channel-subsystem operation, and the functioning of operator controls and indicators, to the extent that operation of the machine does not comply with that described in this publication.

## TOD-Clock Control

When the TOD-clock control is not activated, that is, the control is set to the secure position, the state and value of the TOD clock are protected against unauthorized or inadvertent change by not permitting the instructions SET CLOCK or DIAGNOSE to change the state or value.

When the TOD-clock control is activated, that is, the control is set to the enable-set position, alteration of the clock state or value by means of SET CLOCK or DIAGNOSE is permitted. This setting is momentary, and the control automatically returns to the secure position.

If there is more than one physical representation of the TOD-clock control, the TOD clock is secure only if all TOD-clock controls in the configuration are set to the secure position.

## Wait Indicator

The wait indicator is on when the wait-state bit in the current PSW is one. Instead of a wait indicator, a

model may have a means of indicating a time-averaged value of the wait-state bit.

---

## Multiprocessing Configurations

In a multiprocessing configuration, one of each of the following keys and controls is provided for each CPU: alter and display, interrupt, rate, restart, start, stop, and store status. The load-clear key, load-normal key, and load-unit-address controls are provided for each CPU capable of performing I/O operations. Alternatively, a single set of initial-program-loading keys and controls may be used together with a control to select the desired CPU.

There need not be more than one of each of the following keys and controls in a multiprocessing configuration: address compare, IML, power, system reset clear, system reset normal, and TOD clock.

One check-stop, manual, test, and wait indicator is provided for each CPU. A load indicator is provided only on a CPU capable of performing I/O operations. Alternatively, a single set of indicators may be switched to more than one CPU.

There need not be more than one architectural-mode indicator in a multiprocessing configuration.

In a system capable of reconfiguration, there must be a separate set of keys, controls, and indicators in each configuration.

## Input/Output (I/O)

The terms "input" and "output" are used to describe the transfer of data between I/O devices and main storage. An operation involving this kind of transfer is referred to as an I/O operation. The facilities used to control I/O operations are collectively called the channel subsystem. (I/O devices and their control units attach to the channel subsystem.) This chapter provides a brief description of the basic components and operation of the channel subsystem.

## The Channel Subsystem

The channel subsystem directs the flow of information between I/O devices and main storage. It relieves CPUs of the task of communicating directly with I/O devices and permits data processing to proceed concurrently with I/O processing. The channel subsystem uses one or more channel paths as the communication link in managing the flow of information to or from I/O devices. As part of I/O processing, the channel subsystem also performs a path-management operation by testing for channel-path availability, chooses an available channel path, and initiates the performance of the I/O operation by the device.

Within the channel subsystem are subchannels. One subchannel is provided for and dedicated to each I/O device accessible to the program through the channel subsystem.

The multiple-subchannel-set facility is an optional facility. When it is installed, subchannels are partitioned into multiple subchannel sets, and each subchannel set may provide one dedicated subchannel to an I/O device. Depending on the model and the interface used, some I/O devices may only be allowed to be accessed via certain subchannel sets.

Each subchannel provides information concerning the associated I/O device and its attachment to the channel subsystem. The subchannel also provides information concerning I/O operations and other functions involving the associated I/O device. The subchannel is the means by which the channel subsystem provides information about associated I/O devices to CPUs, which obtain this information by executing I/O instructions. The actual number of subchannels provided depends on the model and the configuration; the maximum addressability is 0-65,535 in each subchannel set.

I/O devices are attached through control units to the channel subsystem by means of channel paths. Control units may be attached to the channel subsystem by more than one channel path, and an I/O device may be attached to more than one control unit. In all, an individual I/O device may be accessible to the channel subsystem by as many as eight different channel paths via a subchannel, depending on the model and the configuration. The total number of channel paths provided by a channel subsystem depends on the model and the configuration; the maximum addressability is 0-255.

The performance of a channel subsystem depends on its use and on the system model in which it is implemented. Channel paths are provided with differ-

ent data-transfer capabilities, and an I/O device designed to transfer data only at a specific rate (a magnetic-tape unit or a disk storage, for example) can operate only on a channel path that can accommodate at least this data rate.

The channel subsystem contains common facilities for the control of I/O operations. When these facilities are provided in the form of separate, autonomous equipment designed specifically to control I/O devices, I/O operations are completely overlapped with the activity in CPUs. The only main-storage cycles required by the channel subsystem during I/O operations are those needed to transfer data and control information to or from the final locations in main storage, along with those cycles that may be required for the channel subsystem to access the subchannels when they are implemented as part of nonaddressable main storage. These cycles do not delay CPU programs, except when both the CPU and the channel subsystem concurrently attempt to reference the same main-storage area.

## Subchannel Sets

When the multiple-subchannel-set facility is installed, subchannels are partitioned into multiple subchannel sets. There may be up to four subchannel sets, each identified by a subchannel-set identifier (SSID). When the multiple-subchannel-set facility is not installed, there is only one subchannel set with an SSID of zero. When the multiple-subchannel-set facility is not enabled, only subchannel set zero is visible to the program. See “Multiple-Subchannel-Set Facility” on page 17-29 for more information on the multiple-subchannel-set facility.

## Subchannels

A subchannel provides the logical appearance of a device to the program and contains the information required for sustaining a single I/O operation. The subchannel consists of internal storage that contains information in the form of a CCW address, channel-path identifier, device number, count, status indications, and I/O-interruption-subclass code, as well as information on path availability and functions pending or being performed. I/O operations are initiated with a

device by the execution of I/O instructions that designate the subchannel associated with the device.

Each device is accessible by means of one subchannel in each channel subsystem to which it is assigned during configuration at installation time. The device may be a physically identifiable unit or may be housed internal to a control unit. For example, in certain disk-storage devices, each actuator used in retrieving data is considered to be a device. In all cases, a device, from the point of view of the channel subsystem, is an entity that is uniquely associated with one subchannel and that responds to selection by the channel subsystem by using the communication protocols defined for the type of channel path by which it is accessible.

On some models, subchannels are provided in blocks. On these models, more subchannels may be provided than there are attached devices. Subchannels that are provided but do not have devices assigned to them are not used by the channel subsystem to perform any function and are indicated by storing the associated device-number-valid bit as zero in the subchannel-information block of the subchannel.

The number of subchannels provided by the channel subsystem is independent of the number of channel paths to the associated devices. For example, a device accessible through alternate channel paths still is represented by a single subchannel. Each subchannel is addressed by using a 16-bit binary subchannel number and a two-bit SSID when the subchannel-set facility is installed.

After I/O processing at the subchannel has been requested by the execution of START SUBCHANNEL, the CPU is released for other work, and the channel subsystem assembles or disassembles data and synchronizes the transfer of data bytes between the I/O device and main storage. To accomplish this, the channel subsystem maintains and updates an address and a count that describe the destination or source of data in main storage. Similarly, when an I/O device provides signals that should be brought to the attention of the program, the channel subsystem transforms the signals into status information and stores the information in the subchannel, where it can be retrieved by the program.

---

## Attachment of Input/Output Devices

### Channel Paths

The channel subsystem communicates with I/O devices by means of channel paths between the channel subsystem and control units. A control unit may be accessible by the channel subsystem by more than one channel path. Similarly, an I/O device may be accessible by the channel subsystem through more than one control unit, each having one or more channel paths to the channel subsystem.

Devices that are attached to the channel subsystem by multiple channel paths configured to a subchannel, may be accessed by the channel subsystem using any of the available channel paths. Similarly, a device having the dynamic-reconnection feature and operating in the multipath mode can be initialized to operate such that the device may choose any of the available channel paths configured to the subchannel, when logically reconnecting to the channel subsystem to continue a chain of I/O operations.

The channel subsystem may contain more than one type of channel path. Examples of channel-path types used by the channel subsystem are the ESCON I/O interface, FICON I/O interface, FICON-converted I/O interface, and IBM System/360 and System/370 I/O interface. The term "serial-I/O interface" is used to refer the ESCON I/O interface, the FICON I/O interface, and the FICON-converted I/O interface. The term "parallel-I/O interface" is used to refer to the IBM System/360 and System/370 I/O interface.

The ESCON I/O interface is described in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

The FICON I/O interface is described in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*

The IBM System/360 and System/370 I/O interface is described in the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974.

Depending on the type of channel path, the facilities provided by the channel path, and the I/O device, an I/O operation may occur in one of three modes, frame-multiplex mode, burst mode, or byte-multiplex mode.

In the frame-multiplex mode, the I/O device may stay logically connected to the channel path for the duration of the execution of a channel program. The facilities of a channel path capable of operating in the frame-multiplex mode may be shared by a number of concurrently operating I/O devices. In this mode the information required to complete an I/O operation is divided into frames that may be interleaved with frames from I/O operations for other I/O devices. During this period, multiple I/O devices are considered to be logically connected to the channel path.

In the burst mode, the I/O device monopolizes a channel path and stays logically connected to the channel path for the transfer of a burst of information. No other device can communicate over the channel path during the time a burst is transferred. The burst can consist of a few bytes, a whole block of data, a sequence of blocks with associated control and status information (the block lengths may be zero), or status information that monopolizes the channel path. The facilities of the channel path capable of operating in the burst mode may be shared by a number of concurrently operating I/O devices.

Some channel paths can tolerate an absence of data transfer for about a half minute during a burst-mode operation, such as occurs when a long gap on magnetic tape is read. An equipment malfunction may be indicated when an absence of data transfer exceeds the prescribed limit.

In the byte-multiplex mode, the I/O device stays logically connected to the channel path only for a short interval of time. The facilities of a channel path capable of operating in the byte-multiplex mode may be shared by a number of concurrently operating I/O devices. In this mode, all I/O operations are split into short intervals of time during which only a segment of information is transferred over the channel path. During such an interval, only one device and its associated subchannel are logically connected to the channel path. The intervals associated with the concurrent operation of multiple I/O devices are sequenced in response to demands from the devices. The channel-subsystem facility associated with a subchannel exercises its controls for any one operation only for the time required to transfer a seg-

ment of information. The segment can consist of a single byte of data, a few bytes of data, a status report from the device, or a control sequence used for the initiation of a new operation.

Ordinarily, devices with high data-transfer-rate requirements operate with the channel path in the frame-multiplex mode, slower devices operate in the burst mode, and the slowest devices operate in the byte-multiplex mode. Some control units have a manual switch for setting the desired mode of operation.

An I/O operation that occurs on a parallel-I/O-interface type of channel path may occur in either the burst mode or the byte-multiplex mode depending on the facilities provided by the channel path and the I/O device. For improved performance, some channel paths and control units are provided with facilities for high-speed transfer and data streaming. See the *System Library publication IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974, for a description of those two facilities.

An I/O operation that occurs on a serial-I/O-interface-type of channel path may occur in either the frame-multiplex mode or the burst mode. For improved performance, some control units attaching to the serial-I/O interface provide the capability to provide sense data to the program concurrent with the presentation of unit-check status, if permitted to do so by the program. (See "Concurrent Sense" on page 17-24.)

Depending on the control unit or channel subsystem, access to a device through a subchannel may be restricted to a single channel-path type.

The modes and features described above affect only the protocol used to transfer information over the channel path and the speed of transmission. No effects are observable by CPU or channel programs with respect to the way these programs are executed.

## Control Units

A control unit provides the logical capabilities necessary to operate and control an I/O device and adapts the characteristics of each device so that it can respond to the standard form of control provided by the channel subsystem.

Communication between the control unit and the channel subsystem takes place over a channel path. The control unit accepts control signals from the

channel subsystem, controls the timing of data transfer over the channel path, and provides indications concerning the status of the device.

The I/O device attached to the control unit may be designed to perform only certain limited operations, or it may perform many different operations. A typical operation is moving a recording medium and recording data. To accomplish its operations, the device needs detailed signal sequences peculiar to its type of device. The control unit decodes the commands received from the channel subsystem, interprets them for the particular type of device, and provides the signal sequence required for the performance of the operation.

A control unit may be housed separately, or it may be physically and logically integrated with the I/O device, the channel subsystem, or a CPU. In the case of most electromechanical devices, a well-defined interface exists between the device and the control unit because of the difference in the type of equipment the control unit and the device require. These electro-mechanical devices often are of a type where only one device of a group attached to a control unit is required to transfer data at a time (magnetic-tape units or disk-access mechanisms, for example), and the control unit is shared among a number of I/O devices. On the other hand, in some electronic I/O devices, such as the channel-to-channel adapter, the control unit does not have an identity of its own.

From the programmer's point of view, most functions performed by the control unit can be merged with those performed by the I/O device. Therefore, this publication normally makes no specific mention of the control-unit function; the performance of I/O operations is described as if the I/O devices communicated directly with the channel subsystem. Reference is made to the control unit only when emphasizing a function performed by it or when describing how the sharing of the control unit among a number of devices affects the performance of I/O operations.

## I/O Devices

An input/output (I/O) device provides external storage, a means of communication between data-processing systems, or a means of communication between a system and its environment. I/O devices include such equipment as magnetic-tape units, direct-access-storage devices (for example, disks),

display units, typewriter-keyboard devices, printers, teleprocessing devices, and sensor-based equipment. An I/O device may be physically distinct equipment, or it may share equipment with other I/O devices.

Most types of I/O devices, such as printers, or tape devices, use external media, and these devices are physically distinguishable and identifiable. Other types are solely electronic and do not directly handle physical recording media. The channel-to-channel adapter, for example, provides for data transfer between two channel paths, and the data never reaches a physical recording medium outside main storage. Similarly, communication controllers may handle the transmission of information between the data-processing system and a remote station, and its input and output are signals on a transmission line.

In the simplest case, an I/O device is attached to one control unit and is accessible from one channel path. Switching equipment is available to make some devices accessible from two or more channel paths by switching devices among control units and by switching control units among channel paths. Such switching equipment provides multiple paths by which an I/O device may be accessed. Multiple channel paths to an I/O device are provided to improve performance or I/O availability, or both, within the system. The management of multiple channel paths to devices is under the control of the channel subsystem and the device, but the channel paths may indirectly be controlled by the program.

## I/O Addressing

Four different types of I/O addressing are provided by the channel subsystem for the necessary addressing of the various components: channel-path identifiers, subchannel numbers, device numbers, and, though not visible to programs, addresses dependent on the channel-path type. When the multiple-subchannel-set facility is installed, the subchannel-set identifier (SSID) is also used in I/O addressing.

### Subchannel-Set Identifier

The subchannel-set identifier (SSID) is a two-bit value assigned to each provided subchannel set.

### Channel-Path Identifier

The channel-path identifier (CHPID) is a system-unique eight-bit value assigned to each installed channel path of the system. A CHPID is used to address a channel path. A CHPID is specified by the second-operand address of RESET CHANNEL PATH and used to designate the channel path that is to be reset. The channel paths by which a device is accessible are identified in the subchannel-information block (SCHIB), each by its associated CHPID, when STORE SUBCHANNEL is executed. The CHPID can also be used in operator messages when it is necessary to identify a particular channel path. A system model may provide as many as 256 channel paths. The maximum number of channel paths and the assignment of CHPIDs to channel paths depends on the system model.

### Subchannel Number

A subchannel number is a system-unique 16-bit value used to address a subchannel. This value is unique within a subchannel set of a channel subsystem. The subchannel is addressed by eight I/O instructions: CANCEL SUBCHANNEL, CLEAR SUBCHANNEL, HALT SUBCHANNEL, MODIFY SUBCHANNEL, RESUME SUBCHANNEL, START SUBCHANNEL, STORE SUBCHANNEL, and TEST SUBCHANNEL. All I/O functions relative to a specific I/O device are specified by the program by designating a subchannel assigned to the I/O device. Subchannels in each subchannel set are always assigned subchannel numbers within a single range of contiguous numbers. The lowest-numbered subchannel is subchannel 0. The highest-numbered subchannel of the channel subsystem has a subchannel number equal to one less than the number of subchannels provided. A maximum of 65,536 subchannels can be provided in each subchannel set. Normally, subchannel numbers are only used in communication between the CPU program and the channel subsystem.

### Device Number

Each subchannel that has an I/O device assigned to it also contains a parameter called the device number. The device number is a 16-bit value that is assigned as one of the parameters of the subchannel at the time the device is assigned to the subchannel.

The device number uniquely identifies a device to the program.

The device number provides a means to identify a device, independent of any limitations imposed by the system model, the configuration, or channel-path protocols. The device number is used in communications concerning the device that take place between the system and the system operator. For example, the device number is entered by the system operator to designate the input device to be used for initial program loading.

**Programming Note:** The device number is assigned at device-installation time and may have any value. However, the user must observe any restrictions on device-number assignment that may be required by the control program, support programs, or the particular control unit or I/O device.

## Device Identifier

A device identifier is an address, not apparent to the program, that is used by the channel subsystem to communicate with I/O devices. The type of device identifier used depends on the specific channel-path type and the protocols provided. Each subchannel contains one or more device identifiers.

For a channel path of the parallel-I/O-interface type, the device identifier is called a device address and consists of an eight-bit value. For the ESCON I/O interface, the device identifier consists of a four-bit control-unit address and an eight-bit device address. For the FICON I/O interface, the device identifier consists of an eight-bit control-unit-image ID and an eight-bit device address. For the FICON-converted I/O interface, the device identifier consists of a four-bit control-unit address and an eight-bit device address.

The device address identifies the particular I/O device (and, on the parallel-I/O interface, the control unit) associated with a subchannel. The device address may identify, for example, a particular magnetic-tape drive, disk-access mechanism, or transmission line. Any number in the range 0-255 can be assigned as a device address.

For further information about the device identifier used with a particular channel-path type, see the appropriate publication for the channel-path type.

## Execution of I/O Operations

I/O operations are initiated and controlled by information with three types of formats: the instruction START SUBCHANNEL, channel-command words (CCWs), and orders. The START SUBCHANNEL instruction is executed by a CPU and is part of the CPU program that supervises the flow of requests for I/O operations from other programs that manage or process the I/O data.

When START SUBCHANNEL is executed, parameters are passed to the target subchannel requesting that the channel subsystem perform a start function with the I/O device associated with the subchannel. The channel subsystem performs the start function by using information at the subchannel, including the information passed during the execution of the START SUBCHANNEL instruction, to find an accessible channel path to the device. Once the device has been selected, the execution of an I/O operation is accomplished by the decoding and execution of a CCW by the channel subsystem and the I/O device. One or more CCWs arranged for sequential execution form a channel program and are executed as one or more I/O operations, respectively. Both instructions and CCWs are fetched from main storage, and their formats are common for all types of I/O devices, although the modifier bits in the command code of a CCW may specify device-dependent conditions for the execution of an operation at the device.

Operations peculiar to a device, such as rewinding tape or positioning the access mechanism on a disk drive, are specified by orders that are decoded and executed by I/O devices. Orders may be transferred to the device as modifier bits in the command code of a control command, may be transferred to the device as data during a control or write operation, or may be made available to the device by other means.

## Start-Function Initiation

CPU programs initiate I/O operations with the instruction START SUBCHANNEL. This instruction passes the contents of an operation-request block (ORB) to the subchannel. The contents of the ORB include the subchannel key, the address of the first CCW to be executed, and a specification of the format of the CCWs. The CCW specifies the command to be executed and the storage area, if any, to be used.

When the ORB contents have been passed to the subchannel, the execution of START SUBCHANNEL is complete. The results of the execution of the instruction are indicated by the condition code set in the program-status word.

When facilities become available, the channel subsystem fetches the first CCW and decodes it according to the format bit specified in the ORB. If the format bit is zero, format-0 CCWs are specified. If the format bit is one, format-1 CCWs are specified. Format-0 and format-1 CCWs contain the same information, but the fields are arranged differently in the format-1 CCW so that 31-bit addresses can be specified directly in the CCW.

## Path Management

If the first CCW passes certain validity tests and does not have the suspend flag specified as one, the channel subsystem attempts device selection by choosing a channel path from the group of channel paths that are available for selection. A control unit that recognizes the device identifier connects itself logically to the channel path and responds to its selection. The channel subsystem sends the command-code part of the CCW over the channel path, and the device responds with a status byte indicating whether the command can be executed. The control unit may logically disconnect from the channel path at this time, or it may remain connected to initiate data transfer.

If the attempted selection does not occur as a result of either a busy indication or a path-not-operational condition, the channel subsystem attempts to select the device by an alternate channel path if one is available. When selection has been attempted on all paths available for selection and the busy condition persists, the operation remains pending until a path becomes free. If a path-not-operational condition is detected on one or more of the channel paths on which device selection was attempted, the program is alerted by a subsequent I/O interruption. The I/O interruption occurs either upon execution of the channel program (assuming the device was selected on an alternate channel path) or as a result of the execution being abandoned because path-not-operational conditions were detected on all of the channel paths on which device selection was attempted.

## Channel-Program Execution

If the command is initiated at the device and command execution does not require any data to be transferred to or from the device, the device may signal the end of the operation immediately on receipt of the command code. In operations that involve the transfer of data, the subchannel is set up so that the channel subsystem will respond to service requests from the device and assume further control of the operation.

An I/O operation may involve the transfer of data to or from one storage area, designated by a single CCW, or to or from a number of noncontiguous storage areas. In the latter case, generally a list of CCWs is used for the execution of the I/O operation, with each CCW designating a contiguous storage area and the CCWs are coupled by data chaining. Data chaining is specified by a flag in the CCW and causes the channel subsystem to fetch another CCW upon the exhaustion or filling of the storage area designated by the current CCW. The storage area designated by a CCW fetched on data chaining pertains to the I/O operation already in progress at the I/O device, and the I/O device is not notified when a new CCW is fetched.

Provision is made in the CCW format for the programmer to specify that, when the CCW is decoded, the channel subsystem request an I/O interruption as soon as possible, thereby notifying a CPU program that chaining has progressed at least as far as that CCW in the channel program.

To complement dynamic address translation in CPUs, CCW indirect data addressing and modified CCW indirect data addressing are provided.

When CCW indirect data addressing is used, a flag in the CCW specifies that an indirect-data-address list is to be used to designate the storage areas for that CCW. Each time the boundary of a block of storage is reached, the list is referenced to determine the next block of storage to be used. The ORB specifies whether the size of each block of storage is 2K bytes or 4K bytes.

When modified CCW indirect data address is used, a flag in the ORB and a flag in the CCW specify that a modified-indirect-data-address list is to be used to designate the storage areas for that CCW. Each time the count of bytes specified for a block of storage is

reached, the list is referenced to determine the next block of storage to be used. Unlike when indirect data addressing is used, the block may be specified on any boundary and length up to 4K, provided a data transfer across a 4K-byte boundary is not specified.

CCW indirect data addressing and modified CCW indirect data addressing permit essentially the same CCW sequences to be used for a program running with dynamic address translation active in the CPU as would be used if the CPU were operating with equivalent contiguous real storage. CCW indirect data addressing permits the program to designate data blocks having absolute storage addresses up to  $2^{64}-1$  independent of whether format-0 or format-1 CCWs have been specified in the ORB. Modified CCW indirect data addressing permits the program to designate data blocks having absolute storage addresses up to  $2^{64}-1$ , independent of whether format-0 or format-1 CCWs have been specified in the ORB.

In general, the execution of an I/O operation or chain of operations involves as many as three levels of participation:

1. Except for effects due to the integration of CPU and channel-subsystem equipment, a CPU is busy for the duration of the execution of START SUBCHANNEL, which lasts until the addressed subchannel has been passed the ORB contents.
2. The subchannel is busy for a new START SUBCHANNEL from the receipt of the ORB contents until the primary interruption condition is cleared at the subchannel.
3. The I/O device is busy from the initiation of the first operation at the device until either the subchannel becomes suspended or the secondary interruption condition is placed at the subchannel. In the case of a suspended subchannel, the device again becomes busy when the execution of the suspended channel program is resumed.

## Conclusion of I/O Operations

The conclusion of an I/O operation normally is indicated by two status conditions: channel end and device end. The channel-end condition indicates that the I/O device has received or provided all data associated with the operation and no longer needs channel-subsystem facilities. This condition is called the

primary interruption condition, and the channel end in this case is the primary status. Generally, the primary interruption condition is any interruption condition that relates to an I/O operation and that signals the conclusion at the subchannel of the I/O operation or chain of I/O operations.

The device-end signal indicates that the I/O device has concluded execution and is ready to perform another operation. This condition is called the secondary interruption condition, and the device end in this case is the secondary status. Generally, the secondary interruption condition is any interruption condition that relates to an I/O operation and that signals the conclusion at the device of the I/O operation or chain of operations. The secondary interruption condition can occur concurrently with, or later than, the primary interruption condition.

Concurrent with the primary or secondary interruption conditions, both the channel subsystem and the I/O device can provide indications of unusual situations.

The conditions signaling the conclusion of an I/O operation can be brought to the attention of the program by I/O interruptions or, when the CPUs are disabled for I/O interruptions, by programmed interrogation of the channel subsystem. In the former case, these conditions cause storing of the I/O-interruption code, which contains information concerning the interrupting source. In the latter case, the interruption code is stored as a result of the execution of TEST PENDING INTERRUPTION.

When the primary interruption condition is recognized, the channel subsystem attempts to notify the program, by means of an interruption request, that a subchannel contains information describing the conclusion of an I/O operation at the subchannel. The information identifies the last CCW used and may provide its residual byte count, thus describing the extent of main storage used. Both the channel subsystem and the I/O device may provide additional indications of unusual conditions as part of either the primary or the secondary interruption condition. The information contained at the subchannel may be stored by the execution of TEST SUBCHANNEL or the execution of STORE SUBCHANNEL. This information, when stored, is called a subchannel-status word (SCSW).

Facilities are provided for the program to initiate the execution of a chain of I/O operations with a single

START SUBCHANNEL instruction. When the current CCW specifies command chaining and no unusual conditions have been detected during the operation, the receipt of the device-end signal causes the channel subsystem to fetch a new CCW. If the CCW passes certain validity tests and the suspend flag is not specified as a one in the new CCW, execution of a new command is initiated at the device. If the CCW fails to pass the validity tests, the new command is not initiated, command chaining is suppressed, and the status associated with the new CCW causes an interruption condition to be generated. If the suspend flag is specified as a one and this value is valid because of a one value in the suspend control, bit 4 of word 1 of the associated ORB, execution of the new command is not initiated, and command chaining is concluded.

Execution of the new command is initiated by the channel subsystem in the same way as in the previous operation. The ending signals occurring at the conclusion of an operation caused by a CCW specifying command chaining are not made available to the program. When another I/O operation is initiated by command chaining, the channel subsystem continues execution of the channel program. If, however, an unusual condition has been detected, command chaining is suppressed, the channel program is terminated, an interruption condition is generated, and the ending signals causing the termination are made available to the program.

The suspend-and-resume function provides the program with control over the execution of a channel program. The initiation of the suspend function is controlled by the setting of the suspend-control bit in the ORB. The suspend function is signaled to the channel subsystem during channel-program execution when the suspend-control bit in the ORB is one and the suspend flag in the first CCW or in a CCW fetched during command chaining is one.

Suspension occurs when the channel subsystem fetches a CCW with the suspend flag validly (because of a one value of the suspend-control bit in the ORB) specified as one. The command in this CCW is not sent to the I/O device, and the device is signaled that the chain of commands is concluded. A subsequent RESUME SUBCHANNEL instruction informs the channel subsystem that the CCW that caused suspension may have been modified and that the channel subsystem must refetch the CCW and examine the current setting of the suspend flag. If the suspend flag is found to be zero in the CCW, the

channel subsystem resumes execution of the chain of commands with the I/O device.

Channel-program execution may be terminated prematurely by CANCEL SUBCHANNEL, HALT SUBCHANNEL or CLEAR SUBCHANNEL. The execution of CANCEL SUBCHANNEL causes the channel subsystem to terminate the start function at the subchannel if the channel program has not been initiated at the device. When the start function is terminated by the execution of CANCEL SUBCHANNEL, the channel subsystem sets condition code 0 in response to the CANCEL SUBCHANNEL instruction. The execution of HALT SUBCHANNEL causes the channel subsystem to issue the halt signal to the I/O device and terminate channel-program execution at the subchannel. When channel-program execution is terminated by the execution of HALT SUBCHANNEL, the program is notified of the termination by means of an I/O-interruption request. The interruption request is generated when the device presents status for the terminated operation. If, however, the halt signal was issued to the device during command chaining after the receipt of device end but before the next command was transferred to the device, the interruption request is generated after the device has been signaled. In the latter case, the device-status field of the SCSW will contain zeros. The execution of CLEAR SUBCHANNEL clears the subchannel of indications of the channel program in execution, causes the channel subsystem to issue the clear signal to the I/O device, and causes the channel subsystem to generate an I/O-interruption request to notify the program of the completion of the clear function.

## I/O Interruptions

Conditions causing I/O-interruption requests are asynchronous to activity in CPUs, and more than one condition can occur at the same time. The conditions are preserved at the subchannels until cleared by TEST SUBCHANNEL or CLEAR SUBCHANNEL, or reset by an I/O-system reset.

When an I/O-interruption condition has been recognized by the channel subsystem and indicated at the subchannel, an I/O-interruption request is made pending for the I/O-interruption subclass specified at the subchannel. The I/O-interruption subclass for which the interruption is made pending is under programmed control through the use of MODIFY SUBCHANNEL. A pending I/O interruption may be accepted by any CPU that is enabled for interruptions

from its I/O-interruption subclass. Each CPU has eight mask bits, in control register 6, that control the enablement of that CPU for each of the eight I/O-interruption subclasses, with the I/O mask, bit 6 in the PSW, being the master I/O-interruption mask for the CPU.

When an I/O interruption occurs at a CPU, the I/O-interruption code is stored in the I/O-communication area of that CPU, and the I/O-interruption request is cleared. The I/O-interruption code identifies the subchannel for which the interruption was pending. The conditions causing the generation of the interruption request may then be retrieved from the subchannel explicitly by TEST SUBCHANNEL or by STORE SUBCHANNEL.

A pending I/O-interruption request may also be cleared by TEST PENDING INTERRUPTION when the corresponding I/O-interruption subclass is enabled but the PSW has I/O interruptions disabled or by TEST SUBCHANNEL when the CPU is disabled for I/O interruptions from the corresponding I/O-interruption subclass. A pending I/O-interruption request may also be cleared by CLEAR SUBCHANNEL. Both CLEAR SUBCHANNEL and TEST SUBCHANNEL clear the preserved interruption condition at the subchannel as well.

Normally, unless the interruption request is cleared by CLEAR SUBCHANNEL, the program issues TEST SUBCHANNEL to obtain information concerning the execution of the operation.

## **Chapter 14. I/O Instructions**

I/O-Instruction Formats . . . . .	14-1	RESET CHANNEL PATH . . . . .	14-9
I/O-Instruction Execution . . . . .	14-2	RESUME SUBCHANNEL . . . . .	14-10
Serialization . . . . .	14-2	SET ADDRESS LIMIT . . . . .	14-12
Operand Access . . . . .	14-2	SET CHANNEL MONITOR . . . . .	14-13
Condition Code . . . . .	14-2	START SUBCHANNEL . . . . .	14-15
Program Exceptions . . . . .	14-2	STORE CHANNEL PATH STATUS . . . . .	14-16
Instructions . . . . .	14-2	STORE CHANNEL REPORT WORD . . . . .	14-17
CANCEL SUBCHANNEL . . . . .	14-4	STORE SUBCHANNEL . . . . .	14-18
CLEAR SUBCHANNEL . . . . .	14-5	TEST PENDING INTERRUPTION . . . . .	14-19
HALT SUBCHANNEL . . . . .	14-6	TEST SUBCHANNEL . . . . .	14-20
MODIFY SUBCHANNEL . . . . .	14-7		

All the I/O instructions described here are provided for the control of channel-subsystem operations. The I/O instructions are listed in Figure 14-1 on page 14-3. All of the I/O instructions are privileged instructions.

Several I/O instructions result in the channel subsystem being signaled to perform functions asynchronous to the execution of the instructions. The description of each instruction of this type contains a section, "Associated Functions," that summarizes the asynchronous functions.

## I/O-Instruction Formats

I/O instructions use the S format:

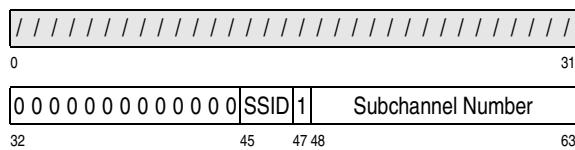

Op Code	$B_2$	$D_2$
0	16	20

The use of the second-operand address and general registers 1 and 2 (as implied operands) depends on the I/O instruction. Figure 14-1 on page 14-3 defines which operands are used to execute each I/O instruction. In addition, detailed information regarding operand usage appears in the description of each I/O instruction.

All I/O instructions that reference a subchannel use the contents of general register 1 as an implied oper-

and. For these I/O instructions, general register 1 contains the subsystem-identification word (SID).

When the multiple-subchannel set (MSS) facility is installed, the format of the subsystem-identification word is as follows:

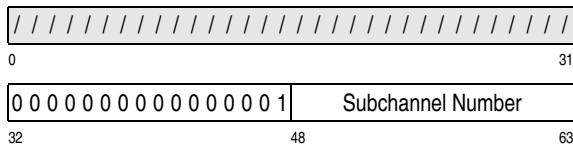

Bit positions 0-31 are ignored. Bit positions 32-44 must contain zeros and bit 47 must contain 1. (Exception conditions are listed later in the section.)

Bit positions 45-46 of general register 1 contain the subchannel-set identifier (SSID) uniquely identifying a subchannel set (SS). When the multiple-subchannel-set facility is not installed, the SSID must be equal to zero. Bit positions 48-63 of general register 1 contain the binary number of the subchannel within the specified subchannel set to be used for the function specified by the instruction.

(See "Multiple-Subchannel-Set Facility" on page 17-29 for more information on SSID.)

The format of the subsystem-identification word when the MSS facility is not installed is as follows:

Bit positions 48-63 of general register 1 contain the binary number of the subchannel to be used for the function specified by the instruction. Bit positions 0-31 of general register 1 are ignored and bits 32-47 specify the binary number one.

## I/O-Instruction Execution

### Serialization

The execution of any I/O instruction causes serialization and checkpoint synchronization to occur. For a definition of the serialization of CPU operations, see “CPU Serialization” on page 5-99.

### Operand Access

During the execution of an I/O instruction, the order in which fields of the operand and fields of the subchannel, if applicable, are accessed is unpredictable. It is also unpredictable whether fetch accesses are made to fields of an operand or the subchannel, as applicable, when those fields are not needed to complete the execution of the I/O instruction. (See “Relation between Operand Accesses” on page 5-98.)

### Condition Code

During the execution of some I/O instructions, the results of certain tests are used to set one of four condition codes in the PSW. The I/O instructions for which execution can result in the setting of the condition code are listed in Figure 14-1 on page 14-3. The condition code indicates the result of the execution of the I/O instruction. The general meaning of the condition code for I/O instructions is given below; the meaning of the condition code for a specific instruction appears in the description of that instruction.

**Condition Code 0:** Instruction execution produced the expected or most probable result. (See “Deferred Condition Code (CC)” on page 16-8 for a description

of conditions that can be encountered subsequent to the presentation of condition code 0 that result in a nonzero deferred condition code.)

**Condition Code 1:** Instruction execution produced the alternate or second-most-probable result, or status conditions were present that may or may not have prevented the expected result.

**Condition Code 2:** Instruction execution was ineffective because the designated subchannel or channel-subsystem facility was busy with a previously initiated function.

**Condition Code 3:** Instruction execution was ineffective because the designated element was not operational or because some condition precluded initiation of the normal function.

In situations where conditions exist that could cause more than one nonzero condition code to be set, the priority of the condition codes is as follows:

Condition code 3 has precedence over condition codes 1 and 2.

Condition code 1 has precedence over condition code 2.

### Program Exceptions

The program exceptions that the I/O instructions can encounter are access, operand, privileged-operation, and specification exceptions. Figure 14-1 on page 14-3 shows the exceptions that are applicable to each of the I/O instructions. The execution of the instruction is suppressed for privileged-operation, operand, and specification exceptions. Except as indicated otherwise in the section “Special Conditions” for each instruction, the instruction ending for access exceptions is as described in “Recognition of Access Exceptions” on page 6-40).

### Instructions

The mnemonics, format, and operation codes of the I/O instructions are given in Figure 14-1 on page 14-3. The figure also indicates the conditions that can cause a program interruption and whether the condition code is set.

In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For START SUBCHANNEL, for

example, SSCH is the mnemonic and D<sub>2</sub>(B<sub>2</sub>) the operand designation.

Name	Mne-monic	Characteristics						Op-code	Page
CANCEL SUBCHANNEL	XSCH	S	C	P	OP	¢	GS		B276 14-4
CLEAR SUBCHANNEL	CSCH	S	C	P	OP	¢	GS		B230 14-5
HALT SUBCHANNEL	HSCH	S	C	P	OP	¢	GS		B231 14-6
MODIFY SUBCHANNEL	MSCH	S	C	P A	SP	OP	¢	B <sub>2</sub>	B232 14-7
RESET CHANNEL PATH	RCHP	S	C	P					B23B 14-9
RESUME SUBCHANNEL	RSCH	S	C	P	OP	¢	GS		B238 14-10
SET ADDRESS LIMIT	SAL	S		P	OP	¢	G1		B237 14-12
SET CHANNEL MONITOR	SCHM	S		P	OP	¢	GM		B23C 14-13
START SUBCHANNEL	SSCH	S	C	P A	SP	OP	¢	B <sub>2</sub>	B233 14-15
STORE CHANNEL PATH STATUS	STCPS	S		P A	SP		¢	ST	B <sub>2</sub> B23A 14-16
STORE CHANNEL REPORT WORD	STCRW	S	C	P A	SP		¢	ST	B <sub>2</sub> B239 14-17
STORE SUBCHANNEL	STSCH	S	C	P A	SP	OP	¢	ST	B <sub>2</sub> B234 14-18
TEST PENDING INTERRUPTION	TPI	S	C	P A <sup>1</sup>	SP		¢	ST	B <sub>2</sub> B236 14-19
TEST SUBCHANNEL	TSCH	S	C	P A	SP	OP	¢	ST	B <sub>2</sub> B235 14-20

**Explanation:**

- ¢ Causes serialization and checkpoint synchronization.
- A Access exceptions for logical addresses.
- A<sup>1</sup> When the effective address is zero, it is not used to access storage, and no access exceptions can occur, except that access exceptions may occur during access-register translation.
- B<sub>2</sub> B<sub>2</sub> field designates an access register in the access-register mode.
- C Condition code is set.
- G1 Instruction execution includes implied use of general register 1 as a parameter.
- GM Instruction execution includes the implied use of multiple general registers.
- GS Instruction execution includes the implied use of general register 1 as the subsystem-identification word.
- OP Operand exception.
- P Privileged-operation exception.
- S S instruction format.
- SP Specification exception.
- ST PER storage-alteration event.

Figure 14-1. Summary of I/O Instructions

## CANCEL SUBCHANNEL

XSCH		[S]
'B276'		
0	16	31

The current start function, if any, is terminated at the designated subchannel if CANCEL SUBCHANNEL is applicable.

General register 1 contains a subsystem-identification word that designates the subchannel for which the current START FUNCTION, if any, is to be terminated.

If the subchannel (1) is not subchannel active, (2) is start pending, resume pending, or suspended, and (3) is performing only the start function, then the start function at the subchannel is terminated, and the subchannel is made no longer start pending, resume pending, or suspended, as appropriate. In addition, internal indications of busy are reset for the subchannel.

Condition code 0 is set to indicate that the actions described above have been taken.

If an invalid ORB field or a no-path-available condition is present for a previously initiated start function and the condition was not reported during the execution of START SUBCHANNEL, condition code 0 may be indicated for CANCEL SUBCHANNEL provided that the subchannel is not yet status pending to report the error condition; if condition code 0 is presented, no subsequent status is generated to indicate the error condition.

### Special Conditions

**Condition code 1** is set, and no other action is taken, when the subchannel is status pending with any status.

**Condition code 2** is set, and no other action is taken, when CANCEL SUBCHANNEL is not applicable and the subchannel is not status pending, or when conditions exist that prevent immediate determination of internal conditions for the subchannel and the CPU has determined to end the instruction. CANCEL SUBCHANNEL is not applicable when the subchannel (1) has no function specified, (2) has a function other than the start function alone specified,

(3) is not resume pending, is not start pending, and is not suspended, or (4) is subchannel active.

**Condition code 3** is set, and no other action is taken, when the subchannel is not operational for CANCEL SUBCHANNEL. A subchannel is not operational for CANCEL SUBCHANNEL when the subchannel is not provided by the channel subsystem, has no valid device number assigned to it, or is not enabled.

CANCEL SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

### Resulting Condition Code:

- 0 Start function canceled
- 1 Status pending
- 2 CANCEL SUBCHANNEL not applicable
- 3 Not operational

### Program Exceptions:

- Operand
- Privileged operation

### Programming Notes:

1. The actions taken by CANCEL SUBCHANNEL are completed during the execution of the instruction.

If condition code 0 is presented, there is no subsequent I/O interruption resulting from the terminated I/O operation. However, the device may have signaled a busy condition while the canceled operation was start pending. In this case, the device owes a no-longer-busy signal to the channel subsystem. This may result in unsolicited device-end status before the next operation is initiated at the device.

Condition code 2 may be presented to indicate that the CPU has determined to end the instruction because the internal conditions of the specified subchannel cannot be immediately determined. Subsequent execution of STORE SUBCHANNEL may store an SCSW indicating that CANCEL SUBCHANNEL is applicable (i.e., the subchannel is performing the start function alone, is start pending, resume pending, or suspended, and is not subchannel-active.) In such a case, the program can either recognize that the I/O operation has not been terminated and allow the operation to start or the program can retry CANCEL SUBCHANNEL in an attempt to terminate the start function. However, retrying CANCEL SUBCHANNEL does not guarantee that the instruction will end with condition code 0.

2. Upon the completion of CANCEL SUBCHANNEL with condition code 0, the subchannel is ready to accept a new start function initiated by START SUBCHANNEL.

## CLEAR SUBCHANNEL

CSCH	[S]	
'B230'	/ / / / / / / / / / / /	
0	16	31

The designated subchannel is cleared, the current start or halt function, if any, is terminated at the designated subchannel, and the channel subsystem is signaled to asynchronously perform the clear function at the designated subchannel and at the associated device.

General register 1 contains a subsystem-identification word (SID) that designates the subchannel to be cleared.

If a start or halt function is in progress, it is terminated at the subchannel.

The subchannel is made no longer status pending. All activity, as indicated in the activity-control field of the SCSW, is cleared at the subchannel, except that the subchannel is made clear pending. Any functions in progress, as indicated in the function-control field of the SCSW, are cleared at the subchannel, except for the clear function that is to be performed because of the execution of this instruction.

The channel subsystem is signaled to asynchronously perform the clear function. The clear function is summarized below in the section “Associated Functions” and is described in detail in “Clear Function” on page 15-13.

Condition code 0 is set to indicate that the actions described above have been taken.

### Associated Functions

Subsequent to the execution of CLEAR SUBCHANNEL, the channel subsystem asynchronously performs the clear function. If conditions allow, the channel subsystem chooses a channel path and attempts to issue the clear signal to the device to terminate the I/O operation, if any. The subchannel then becomes status pending. Conditions encountered by the channel subsystem that preclude issuing the clear signal to the device do not prevent the subchannel from becoming status pending (see “Clear Function” on page 15-13).

When the subchannel becomes status pending as a result of performing the clear function, data transfer, if any, with the associated device has been terminated. The SCSW stored when the resulting status is cleared by TEST SUBCHANNEL has the clear-function bit stored as one. If the channel subsystem can determine that the clear signal was issued to the device, the clear-pending bit is stored as zero in the SCSW. Otherwise, the clear-pending bit is stored as one, and other indications are provided that describe in greater detail the condition that was encountered. (See “Interruption-Response Block” on page 16-6.)

Measurement data is not accumulated, and device-connect time is not stored in the extended-status word for the subchannel, for a start function that is terminated by CLEAR SUBCHANNEL.

### Special Conditions

**Condition code 3** is set, and no other action is taken, when the subchannel is not operational for CLEAR SUBCHANNEL. A subchannel is not operational for CLEAR SUBCHANNEL when the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled.

CLEAR SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

#### ***Resulting Condition Code:***

- 0 Function initiated
- 1 —
- 2 —
- 3 Not operational

#### ***Program Exceptions:***

- Operand
- Privileged operation

## **HALT SUBCHANNEL**

HSCH	[S]
'B231'	/ / / / / / / / / / / /
0	16 31

The current start function, if any, is terminated at the designated subchannel, and the channel subsystem is signaled to asynchronously perform the halt function at the designated subchannel and at the associated device.

General register 1 contains a subsystem-identification word that designates the subchannel to be halted.

If a start function is in progress, it is terminated at the subchannel.

The subchannel is made halt pending, and the halt function is indicated at the subchannel.

When HALT SUBCHANNEL is executed and the designated subchannel is subchannel-and-device active and status pending with intermediate status, the status-pending indication is eliminated (see the discussion of bits 24, 25, and 28 in "Activity Control (AC)" on page 16-13). The status-pending condition is

reestablished as part of the halt function (see the section "Associated Functions" below).

The channel subsystem is signaled to asynchronously perform the halt function. The halt function is summarized below in the section "Associated Functions" and is described in detail in "Halt Function" on page 15-15.

Condition code 0 is set to indicate that the actions described above have been taken.

#### ***Associated Functions***

Subsequent to the execution of HALT SUBCHANNEL, the channel subsystem asynchronously performs the halt function. If conditions allow, the channel subsystem chooses a channel path and attempts to issue the halt signal to the device to terminate the I/O operation, if any. The subchannel then becomes status pending.

When the subchannel becomes status pending as a result of performing the halt function, data transfer, if any, with the associated device has been terminated. The SCSW stored when the resulting status is cleared by TEST SUBCHANNEL has the halt-function bit stored as one. If the halt signal was issued to the device, the halt-pending bit is stored as zero. Otherwise, the halt-pending bit is stored as one, and other indications are provided that describe in greater detail the condition that was encountered. (See "Interruption-Response Block" on page 16-6, and "Halt Function" on page 15-15.)

On some models, path availability is tested as part of the halt function instead of as part of the execution of the instruction. In these models, when no channel path is available for selection, the halt signal is not issued, and the subchannel is made status pending. When the status-pending condition is subsequently cleared by TEST SUBCHANNEL, the halt-pending bit is stored as one in the SCSW.

If a status-pending condition is eliminated during the execution of HALT SUBCHANNEL, then this condition is reestablished along with the other status conditions when the completion of the halt function is indicated to the program.

The halt-pending condition may not be recognized by the channel subsystem if a status-pending condition has been generated. This situation could occur, for example, when alert status is presented or generated

while the subchannel is already start pending or resume pending, or when primary status is presented during the attempt to initiate the I/O operation for the first command as specified by the start function or implied by the resume function. If recognition of the status-pending condition by the channel subsystem has occurred logically prior to recognition of the halt-pending condition, the SCSW, when cleared by TEST SUBCHANNEL, has the halt-pending bit stored as one.

If measurement data is being accumulated when a start function is terminated by HALT SUBCHANNEL, the measurement data continues to be accumulated for the subchannel and reflects the extent of subchannel and device usage required, if any, while performing the currently terminated start function. The measurement data, if any, is accumulated in the measurement block for the subchannel or placed in the extended-status word, as appropriate, when the subchannel becomes status-pending with primary or secondary status. (See "Channel-Subsystem Monitoring" on page 17-1.)

### Special Conditions

**Condition code 1** is set, and no other action is taken, when the subchannel is status pending alone or is status pending with any combination of alert, primary, or secondary status.

**Condition code 2** is set, and no other action is taken, when the subchannel is busy for HALT SUBCHANNEL. The subchannel is busy for HALT SUBCHANNEL when a halt function or clear function is already in progress at the subchannel.

**Condition code 3** is set, and no other action is taken, when the subchannel is not operational for HALT SUBCHANNEL. A subchannel is not operational for HALT SUBCHANNEL when the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled. On some models, a subchannel is also not operational for HALT SUBCHANNEL when no channel path is available for selection by the device. (See "Channel-Path Availability" on page 15-12 for a description of channel paths that are available for selection.)

HALT SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

### Resulting Condition Code:

- 0 Function initiated
- 1 Status pending with other than intermediate status
- 2 Busy
- 3 Not operational

### Program Exceptions:

- Operand
- Privileged operation

**Programming Note:** After the execution of HALT SUBCHANNEL, the status-pending condition indicating the completion of the halt function may be delayed for an extended period of time, for example, when the device is a magnetic-tape unit executing a rewind command.

## MODIFY SUBCHANNEL

MSCH	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B232'	B <sub>2</sub> D <sub>2</sub>

The information contained in the subchannel-information block (SCHIB) is placed in the program-modifiable fields at the subchannel. As a result, the program influences, for that subchannel, certain aspects of I/O processing relative to the clear, halt, resume, and start functions and certain I/O support functions.

General register 1 contains a subsystem-identification word (SID) that designates the subchannel that is to be modified as specified by certain fields of the SCHIB. The second-operand address is the logical address of the SCHIB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The channel-subsystem operations that may be influenced due to placement of SCHIB information in the subchannel are:

- I/O processing (E field)
- Interruption processing (interruption parameter and ISC field)
- Path management (D, LPM, and POM fields)
- Monitoring and address-limit checking (measurement-block index, LM, and MM fields)
- Measurement-block-format control (F field)
- Extended-measurement-word-mode enable (X field)
- Concurrent-sense facility (S field)
- Measurement-block address (MBA)

Bits 0, 1, 6, and 7 of word 1, and bits 0-28 of word 6 of the SCHIB operand must be zeros, and bits 9 and 10 of word 1 must not both be ones. When the extended-I/O-measurement-block facility is installed, bits 26-31 of word 11 must be specified as zeros. When the extended-I/O-measurement-block facility is not installed, bit 29 of word 6 must be specified as zero; otherwise, an operand exception is recognized. When the extended-I/O-measurement-word facility is not installed, or is installed but not enabled, bit 30 of word 6 must be specified as zero; otherwise, an operand exception is recognized. The remaining fields of the SCHIB are ignored and do not affect the processing of MODIFY SUBCHANNEL. (For further details, see “Subchannel-Information Block” on page 15-1.)

Condition code 0 is set to indicate that the information from the SCHIB has been placed in the program-modifiable fields at the subchannel, except that, when the device-number-valid bit (V) at the designated subchannel is zero, then condition code 0 is set, and the information from the SCHIB is not placed in the program-modifiable fields.

### Special Conditions

**Condition code 1** is set, and no other action is taken, when the subchannel is status pending. (See “Status Control (SC)” on page 16-16.)

**Condition code 2** is set, and no other action is taken, when a clear, halt, or start function is in progress at the subchannel. (See “Function Control (FC)” on page 16-12.)

**Condition code 3** is set, and no other action is taken, when the subchannel is not operational for

MODIFY SUBCHANNEL. A subchannel is not operational for MODIFY SUBCHANNEL when the subchannel is not provided in the channel subsystem.

MODIFY SUBCHANNEL can encounter the program exceptions described or listed below.

In word 1 of the SCHIB, bits 0, 1, 6, and 7 must be zeros, and bits 9 and 10 must not both be ones. In word 6 of the SCHIB, bits 0-28 must be zeros. Otherwise an operand exception is recognized.

When the extended-I/O-measurement-block facility is installed, bits 26-31 of word 11 must be specified as zeros; otherwise, an operand exception is recognized. When the extended-I/O-measurement-block facility is not installed, bit 29 of word 6 must be specified as zero; otherwise, an operand exception is recognized. When the extended-I/O-measurement-word facility is not installed, or is installed but not enabled, bit 30 of word 6 must be specified as zero; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of MODIFY SUBCHANNEL is suppressed on all addressing and protection exceptions.

### Resulting Condition Code:

- 0 Function completed
- 1 Status pending
- 2 Busy
- 3 Not operational

### Program Exceptions:

- Access (fetch, operand 2)
- Operand
- Privileged operation
- Specification

## Programming Notes:

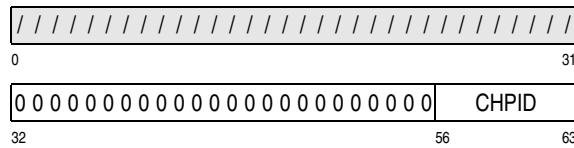

1. If a device signals I/O-error alert while the associated subchannel is disabled, the channel subsystem issues the clear signal to the device and discards the I/O-error-alert indication without generating an I/O-interruption condition.
  2. If a device presents unsolicited status while the associated subchannel is disabled, that status is discarded by the channel subsystem without generating an I/O-interruption condition. However, if the status presented contains unit check, the channel subsystem issues the clear signal for the associated subchannel and does not generate an I/O-interruption condition. This should be taken into account when the program uses MODIFY SUBCHANNEL to enable a subchannel. For example, the medium on the associated device that was present when the subchannel became disabled may have been replaced, and, therefore, the program should verify the integrity of that medium.
  3. It is recommended that the program inspect the contents of the subchannel by subsequently issuing STORE SUBCHANNEL when MODIFY SUBCHANNEL sets condition code 0. Use of STORE SUBCHANNEL is a method for determining if the designated subchannel was changed or not. Failure to inspect the subchannel following the setting of condition code 0 by MODIFY SUBCHANNEL may result in conditions that the program does not expect to occur.

## **RESET CHANNEL PATH**

RCHP	[S]
'B23B'	/ / / / / / / / / / / /

The channel-path-reset facility is signaled to perform the channel-path-reset function on the channel path designated by the contents of general register 1.

The format of general register 1 is as follows:

**Channel-Path Identifier (CHPID):** Bit positions 56-63 of general register 1 contain an unsigned binary integer that designates the channel path on which the channel-path-reset function is to be performed.

Bit positions in general register 1 that are shown as zeros, are reserved and must contain zeros; otherwise, an operand exception is recognized. Bit positions 0-31 of general register 1 are ignored.

If conditions allow, the channel-path-reset facility is signaled to asynchronously perform the channel-path-reset function on the designated channel path. The channel-path-reset function is summarized below in the section “Associated Functions” and is described in detail in “Channel-Path Reset” on page 17-12.

Condition code 0 is set to indicate that the channel-path-reset facility has been signaled.

## Associated Functions

Subsequent to the execution of RESET CHANNEL PATH, the channel-path-reset facility asynchronously performs the channel-path-reset function. Certain indications are reset at all subchannels that have access to the designated channel path, and the reset signal is issued on that channel path. Any I/O functions in progress at the devices are reset, but only for the channel path on which the reset signal is received. An I/O operation or chain of I/O operations taking place in the multipath mode may be able to continue to be executed on other channel paths in the multipath group, if any. (See "Channel-Path-Reset Function" on page 15-45.)

The result of performing the channel-path-reset function on the designated channel path is communicated to the program by means of a channel report (see “Channel Report” on page 17-24).

## **Special Conditions**

**Condition code 2** is set, and no other action is taken, when, on some models, the channel-path-reset facility is busy performing the channel-path-reset function for a previous execution of the RESET CHANNEL PATH instruction.

**Condition code 3** is set, and no other action is taken, when, on some models, the designated channel path is not operational for the execution of RESET CHANNEL PATH. On these models, the channel path is not operational for the execution of RESET CHANNEL PATH when the designated channel path is not physically available.

If the channel-path-reset facility is busy and the designated channel path is not physically available, it depends on the model whether condition code 2 or 3 is set.

RESET CHANNEL PATH can encounter the program exceptions described or listed below.

Bit positions 32-55 of general register 1 must contain zeros; otherwise, an operand exception is recognized. Bit positions 0-31 of general register 1 are ignored.

#### **Resulting Condition Code:**

- 0 Function initiated
- 1 —
- 2 Busy
- 3 Not operational

#### **Program Exceptions:**

- Operand
- Privileged operation

#### **Programming Notes:**

1. To eliminate the possibility of a data-integrity exposure for devices that have the capability of generating unsolicited device-end status, I/O operations in progress with such devices on the channel path for which RESET CHANNEL PATH is to be executed must be terminated by the execution of either HALT SUBCHANNEL or CLEAR SUBCHANNEL. Otherwise, subsequent to receiving the reset signal, the device may present an unsolicited device end that may be interpreted by the channel subsystem as a solicited device end and cause command chaining to occur.

2. If the status-verification facility is being used and RESET CHANNEL PATH is executed without first stopping all ongoing operations associated with the channel path being reset, erroneous device-status-check conditions may be detected

## **RESUME SUBCHANNEL**

RSCH	[S]
'B238'	/ / / / / / / / / / / /
0	16

The channel subsystem is signaled to perform the resume function at the designated subchannel.

General register 1 contains a subsystem-identification word that designates the subchannel at which the resume function is to be performed.

The subchannel is made resume pending.

Logically prior to the setting of condition code 0 and only if the subchannel is currently in the suspended state, path-not-operational conditions at the subchannel, if any, are cleared.

The channel subsystem is signaled to asynchronously perform the resume function. The resume function is summarized below in the section "Associated Functions" and is described in detail in "Start Function and Resume Function" on page 15-18

Condition code 0 is set to indicate that the actions described above have been taken.

#### **Associated Functions**

Subsequent to the execution of RESUME SUBCHANNEL, the channel subsystem asynchronously performs the resume function. Except when the subchannel is subchannel active, if the execution of RESUME SUBCHANNEL results in the setting of condition code 0, performance of the resume function causes execution of a currently suspended channel program to be resumed with the associated device, provided that the suspend flag for the current CCW has been set to zero by the program. If the suspend flag remains one, execution of the channel program remains suspended. But, if the subchannel is subchannel active at the time the execution of RESUME SUBCHANNEL results in the setting of condition code 0, then it is unpredictable whether

execution of the current program is resumed or whether it is found by the resume function that the subchannel has become suspended in the interim. The subchannel is found to be suspended by the resume function only if the subchannel is status pending with intermediate status when the resume-pending condition is recognized by the channel subsystem. (See "Start Function and Resume Function" on page 15-18.)

### Special Conditions

**Condition code 1** is set, and no other action is taken, when the subchannel is status pending.

**Condition code 2** is set, and no other action is taken, when the resume function is not applicable. The resume function is not applicable when the subchannel (1) has any function other than the start function alone specified, (2) has no function specified, (3) is resume pending, or (4) does not have suspend control specified for the start function in progress.

**Condition code 3** is set, and no other action is taken, when the subchannel is not operational for the resume function. A subchannel is not operational for the resume function if the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled.

RESUME SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

### Resulting Condition Code:

- 0 Function initiated
- 1 Status pending
- 2 Function not applicable
- 3 Not operational

### Program Exceptions:

- Operand
- Privileged operation

### Programming Notes:

1. When channel-program execution is resumed from the suspended state, the device views the resumption as the beginning of a new chain of commands. When the suspension of channel-program execution occurs and the device requires that certain commands be first or appear only once in a chain of commands (for example, direct-access-storage devices), the program must ensure that the appropriate commands in the proper sequence are fetched by the channel subsystem after channel-program execution is resumed. One way the program can ensure proper sequencing of commands at the device is by allowing the I/O interruption to occur for an intermediate interruption condition due to suspension.

It is not reliable to notify the program that the subchannel is suspended by using the PCI flag in the CCW that contains the S flag because the PCI I/O interruption may occur before the subchannel is suspended. The SCSW would indicate that an I/O operation is in progress at the subchannel and device in this case.

The suspend flag of the target CCW should be set to zero before RESUME SUBCHANNEL is executed; otherwise, it is possible that the resume-pending condition may be recognized and the CCW refetched while the suspend flag is still one, in which case the resume-pending condition would be reset, and the execution of the channel program would be suspended. If the suspend flag of the target CCW is set to zero before the execution of RESUME SUBCHANNEL, the channel program is not suspended, provided that the subchannel is not subchannel active at the time the execution of RESUME SUBCHANNEL results in the setting of condition code 0. If condition code 0 is set while the subchannel is still subchannel active, it is unpredictable whether the resume-pending condition is recognized by the channel subsystem or whether it is found by the resume function that the subchannel has become suspended in the interim. The subchannel is found to be suspended by the resume function only if the subchannel is status pending with intermediate status at the time the resume-pending condition is recognized. When

the subchannel is suspended, the execution of TEST SUBCHANNEL, which clears the intermediate interruption condition, also clears the indication of resume pending.

2. Some models recognize a resume-pending condition only after a CCW having an S flag validly set to one is fetched. Therefore, if a subchannel is resume pending and, during the execution of the channel program, no CCW is fetched having an S flag validly set to one, the subchannel remains resume pending until the primary interruption condition is cleared by TEST SUBCHANNEL.
  3. Path availability is not tested during the execution of RESUME SUBCHANNEL. Instead, path availability is tested when the channel subsystem begins performance of the resume function.
  4. The contents of the CCW fetched during performance of the resume function may be different from the contents of the same CCW when it was previously fetched and contained an S flag validly set to one.

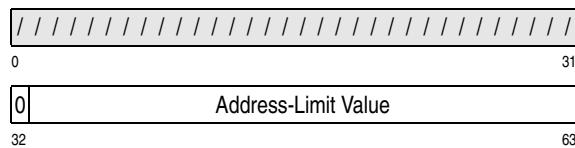

# SET ADDRESS LIMIT

SAL	[S]
'B237'	

The address-limit-checking facility is signaled to use the specified address as the address-limit value, and the specified address is passed to the facility. Depending on the model, this instruction may not be provided. When this instruction is not provided, it is checked for operand exception and privileged-operation exception, and then is suppressed.

General register 1 contains the absolute address to be used as the address-limit value. The specified address must be on a 64K-byte boundary and may designate a maximum absolute storage address of 2,147,418,112 (7FFF0000 hex) regardless of whether the CPU is operating in the 24-bit, 31-bit, or 64-bit addressing mode. Bits 0-31 of general register 1 are ignored, and bit 32 must be zero.

General register 1 has the following format:

## Associated Functions

The value that is used by the address-limit-checking facility when determining whether to permit or prohibit a data access is called the address-limit value. The initial address-limit value is zero. The initial address-limit value is used by the address-limit-checking facility until the facility recognizes a signal, caused by the execution of SET ADDRESS LIMIT, to use a specified address. The recognition of this specified address as the new address-limit value occurs asynchronously with respect to the execution of SET ADDRESS LIMIT.

If address-limit checking is specified for a subchannel, then whether the specified address is used by the address-limit-checking facility, when determining whether to permit or prohibit a data access, depends on whether SET ADDRESS LIMIT was executed before, during, or after the execution of START SUBCHANNEL for that subchannel. If SET ADDRESS LIMIT is executed before START SUBCHANNEL, the specified address is used by the address-limit-checking facility. If SET ADDRESS LIMIT is executed during or after the execution of START SUBCHANNEL, it is unpredictable whether the specified address is used by the address-limit-checking facility for that particular start function. For a description of the manner in which address-limit checking is performed, see "Address-Limit Checking" on page 17-22.

### **Special Conditions**

SET ADDRESS LIMIT can encounter the program exceptions described or listed below.

The address in general register 1 must be designated on a 64K byte boundary, and bit 32 of general register 1 must be zero; otherwise, an operand exception is recognized.

**Condition Code:** The code remains unchanged.

## ***Program Exceptions:***

- Operand

- Privileged operation

## **SET CHANNEL MONITOR**

SCHM	[S]
'B23C'	/ / / / / / / / / / / /
0	16

Each of the measurement-block-update mode and device-connect-time-measurement mode of the channel subsystem is made either active or inactive, depending on the values of the measurement-mode-control bits in general register 1. If the measurement-mode-control bit for measurement-block update is one, the measurement-block origin and measurement-block key are passed to the channel subsystem.

General register 1 has the following format:

**Ignored:** Bit positions 0-31 of general register 1 are ignored.

**Measurement-Block Key (MBK):** Bit positions 32-35 of general register 1 contain the measurement-block key. When bit 62 is one, MBK specifies the access key that is to be used by the channel subsystem when it accesses the measurement-block area and, when the extended-I/O-measurement-block facility is installed, to access format-1 measurement blocks. Otherwise, MBK is ignored.

**Measurement-Block-Update Control (M):** Bit 62 of general register 1 is the measurement-mode-control bit that controls the measurement-block-update mode. When bit 62 of general register 1 is one and conditions allow, the measurement-block-update facility is signaled to asynchronously make the measurement-block-update mode active. In addition, the measurement-block-origin (MBO) address in general register 2 and the measurement-block key (MBK) in general register 1 are passed to the measurement-block-update facility.

The measurement-block origin is used to determine the location of format-0 measurement blocks; the address of format-1 measurement blocks is stored at the subchannel using MODIFY SUBCHANNEL. The measurement-block key is used to access both format-0 and format-1 measurement blocks. The asynchronous functions that are performed by the measurement-block-update facility are summarized below in the section "Associated Functions" and are described in detail in "Channel-Subsystem Monitoring" on page 17-1.

When bit 62 of general register 1 is zero and conditions allow, the measurement-block-update mode is made inactive if it is active or remains inactive if it is inactive. The contents of bit positions 32-35 (MBK) of general register 1 and the contents of general register 2 are ignored.

## **Device-Connect-Time-Measurement**      **Control**

**(D):** Bit 63 of general register 1 is the measurement-mode-control bit (D). When bit 63 is one and conditions allow, the device-connect-time-measurement mode is made active if it is inactive or remains active if it is active. When bit 63 is zero and conditions allow, the device-connect-time-measurement mode is made inactive if it is active or remains inactive if it is inactive.

Bit positions 36-61 of general register 1 are reserved and must contain zeros; otherwise, an operand exception is recognized.

General register 2 has the following format:

MBO Address

### **Measurement-Block-Origin (MBO) Address:**

**Measurement-Block Origin (MBO) Address.** When bit 62 (M) of general register 1 is one, bit positions 0-63 of general register 2 contain the absolute address of the measurement-block origin (MBO), which is the beginning of the measurement-block area. The MBO address is used by the channel subsystem to locate format-0 measurement blocks. The origin of the measurement-block area must be designated on a 32-byte boundary otherwise, an operand exception is recognized. When bit 62 of general register 1 is zero, the contents of general register 2 are ignored.

If the channel-subsystem timer that is used by the channel-subsystem-monitoring facilities is in the error state, the state is reset. This happens independent of the setting of the two measurement-mode-control bits. (See “Channel-Subsystem Timing” on page 17-2 for a description of the timing facilities.)

### **Associated Functions**

When the measurement-block-update facility is signaled (by means of SET CHANNEL MONITOR) to make the measurement-block-update mode active, the functions that are performed by the facility depend on whether or not the mode is already active when the signal is generated.

If the measurement-block-update mode is inactive when the signal is generated, the mode remains inactive until the measurement-block-update facility recognizes the signal. When the measurement-block-update facility recognizes the signal, the measurement-block-update mode is made active, and the MBK that was passed when the signal was generated is used to access all measurement blocks, and the MBO that was passed when the signal was generated is used to determine the address of format-0 measurement blocks.

If the measurement-block-update mode is active when the signal is generated, the mode remains active, and the MBK and MBO associated with the execution of a previous SET CHANNEL MONITOR instruction continue to be used to control the storing of measurement data until the measurement-block-update facility recognizes the signal. When the measurement-block-update facility recognizes the signal, the MBK and MBO associated with that signal are used instead of the MBK and MBO associated with the execution of a previous SET CHANNEL MONITOR instruction. The SET CHANNEL MONITOR instruction does not affect the measurement-block address used for format-1 measurement blocks, but the MBK associated with the signal becomes the key used to access the measurement block.

In all above cases, the measurement-block-update facility recognizes the signal during, or subsequent to, the execution of the SET CHANNEL MONITOR instruction that caused the signal to be generated and logically prior to the performance of any start function that is initiated by the subsequent execution of START SUBCHANNEL for a subchannel that is enabled for measurement by this facility. If a subchannel that is enabled for measurement by this facil-

ity already has a start function in progress when the signal is generated, it is unpredictable when measurement data for that subchannel is stored by using the MBK and MBO associated with that signal.

While the measurement-block-update mode is active, performance measurements are accumulated for subchannels that are enabled for measurement-block update. Measurements for a subchannel are either accumulated in a single 32-byte format-0 measurement block within the measurement-block area, or a 64-byte format-1 measurement block pointed to by the measurement-block address at the subchannel. A subchannel is enabled for the measurement-block-update mode by setting the measurement-block-update-enable bit to one in the SCHIB and then executing the MODIFY SUBCHANNEL instruction for that subchannel. The measurement-block-format-control bit (F) at the subchannel specifies whether a format-0 or format-1 measurement block is stored for a subchannel when the measurement-block-update mode is active and the subchannel is enabled for measurement-block updates. When the F bit is zero, the MBO and MBI are used to determine the address of the measurement block for the subchannel, and a format-0 measurement block is stored. When the F bit is one, the measurement-block-address field at the subchannel contains the address of the measurement block for the subchannel, and a format-1 measurement block is stored. The F bit and measurement-block-address field are modified using the MODIFY SUBCHANNEL instruction.

When the device-connect-time-measurement mode is active, measurements of the length of time that the device is actively communicating with the channel subsystem during the execution of a channel program are accumulated for subchannels that are enabled for device-connect-time measurement. Measurements for a subchannel are provided in the extended-status word ESW of the IRB. A subchannel is enabled for device-connect-time-measurement mode by setting the device-connect-time-measurement-enable bit to one in the SCHIB and then executing MODIFY SUBCHANNEL for that subchannel.

For a more detailed description of the measurement-block-update mode, the format and contents of the measurement block, and the device-connect-time-measurement mode, see “Channel-Subsystem Monitoring” on page 17-1.

### **Special Conditions**

SET CHANNEL MONITOR can encounter the program exceptions described or listed below.

Bits 36-61 of general register 1 must be zeros. When bit 62 (M) of general register 1 is one, the MBO address in general register 2 must be designated on a 32-byte boundary. Otherwise, an operand exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Operand
- Privileged operation

**Programming Note:** When the channel subsystem is initialized, the measurement-block-update and device-connect-time-measurement modes are made inactive.

## START SUBCHANNEL

SSCH	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B233'        B <sub>2</sub> D <sub>2</sub>	16      20      31

The channel subsystem is signaled to asynchronously perform the start function for the associated device, and the execution parameters that are contained in the designated ORB are placed at the designated subchannel. (See "Operation-Request Block" on page 15-21.)

General register 1 contains a subsystem-identification word that designates the subchannel to be started. The second-operand address is the logical address of the ORB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution parameters contained in the ORB are placed at the subchannel.

When START SUBCHANNEL is executed, the subchannel is status pending with only secondary status, and the extended-status-word-format bit (L) is zero, the status-pending condition is discarded at the subchannel.

The subchannel is made start pending, and the start function is indicated at the subchannel.

Logically prior to the setting of condition code 0, path-not-operational conditions at the subchannel, if any, are cleared.

The channel subsystem is signaled to asynchronously perform the start function. The start function is summarized below in the section "Associated Functions" and is described in detail in "Start Function and Resume Function" on page 15-18.

Condition code 0 is set to indicate that the actions described above have been taken.

### Associated Functions

Subsequent to the execution of START SUBCHANNEL, the channel subsystem asynchronously performs the start function.

The contents of the ORB, other than the fields that must contain all zeros, are checked for validity. On some models, the fields of the ORB that must contain zeros are checked asynchronously, instead of during the execution of the instruction. When invalid fields are detected asynchronously, the subchannel becomes status pending with primary, secondary, and alert status and with deferred condition code 1 and program check indicated. (See "Program Check" on page 16-24.) In this situation, the I/O operation or chain of I/O operations is not initiated at the device, and the condition is indicated by the start-pending bit being stored as one when the SCSW is cleared by the execution of TEST SUBCHANNEL. (See "Subchannel-Status Word" on page 16-6).

On some models, path availability is tested asynchronously, instead of during the execution of the instruction. When no channel path is available for selection, the subchannel becomes status pending with primary and secondary status and with deferred condition code 3 indicated. The I/O operation or chain of I/O operations is not initiated at the device, and this condition is indicated by the start-pending bit being stored as one when the SCSW is cleared by the execution of TEST SUBCHANNEL.

If conditions allow, a channel path is chosen, and execution of the channel program that is designated in the ORB is initiated. (See "Start Function and Resume Function" on page 15-18.)

### Special Conditions

**Condition code 1** is set, and no other action is taken, when the subchannel is status pending when START SUBCHANNEL is executed. On some models, condition code 1 is not set when the subchannel is status pending with only secondary status; instead, the status-pending condition is discarded.

**Condition code 2** is set, and no other action is taken, when a start, halt, or clear function is currently in progress at the subchannel (see “Function Control (FC)” on page 16-12).

**Condition code 3** is set, and no other action is taken, when the subchannel is not operational for START SUBCHANNEL. A subchannel is not operational for START SUBCHANNEL if the subchannel is not provided in the channel subsystem, has no valid device number associated with it, or is not enabled.

A subchannel is also not operational for START SUBCHANNEL, on some models, when no channel path is available for selection. On these models, the lack of an available channel path is detected as part of the START SUBCHANNEL execution. On other models, channel-path availability is only tested as part of the asynchronous start function.

START SUBCHANNEL can encounter the program exceptions described or listed below.

In word 1 of the ORB, bits 13 and 25-30 must be zeros, and, in word 2 of the ORB, bit 0 must be zero. Otherwise, on some models, an operand exception is recognized. On other models, an I/O-interruption condition is generated, indicating program check, as part of the asynchronous start function.

START SUBCHANNEL can also encounter the program exceptions listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of START SUBCHANNEL is suppressed on all addressing and protection exceptions.

#### **Resulting Condition Code:**

- 0 Function initiated
- 1 Status pending
- 2 Busy
- 3 Not operational

#### **Program Exceptions:**

- Access (fetch, operand 2)
- Operand
- Privileged operation
- Specification

## **STORE CHANNEL PATH STATUS**

STCPS	D <sub>2</sub> (B <sub>2</sub> )	[S]
'B23A'	B <sub>2</sub>	D <sub>2</sub>

0                  16            20            31

Depending on the model, this instruction may not be provided. When this instruction is not provided, it is checked for privileged operation exception and the instruction is suppressed by the machine

A channel-path-status word of up to 256 bits is stored at the designated location.

The second-operand address is the logical address of the location where the channel-path-status word is to be stored and must be designated on a 32-byte boundary; otherwise, a specification exception is recognized.

The channel-path-status word indicates which channel paths are actively communicating with a device at the time STORE CHANNEL PATH STATUS is executed. Bit positions 0-255 correspond, respectively, to the channel paths having the channel-path identifiers 0-255. Each of the 256 bits at the designated location is set to one, set to zero, or left unchanged, as follows:

- For all channel paths in the configuration that are actively communicating with devices at the time STORE CHANNEL PATH STATUS is executed, the corresponding bits are stored as ones.

- For all channel paths that are (1) provided in the system (PIM bit in the PMCW is one) and (2) in the configuration but not currently being used by the channel subsystem in actively communicating with devices, the corresponding bits are stored as zeros.
- For all channel paths that are not provided in the system (PIM bit in the PMCW is zero), the corresponding bits either are not stored or are stored as zeros.
- For all channel paths in the configuration that are in the channel-path-terminal state or are not physically available (the corresponding PAM bit in the PMCW is zero), the corresponding bits are stored as zeros.

### Special Conditions

STORE CHANNEL PATH STATUS can encounter the program exceptions described or listed below.

The second operand must be designated on a 32-byte boundary; otherwise, a specification exception is recognized.

The execution of STORE CHANNEL PATH STATUS is suppressed on all addressing and protection exceptions.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification

### Programming Notes:

- To ensure a consistent interpretation of channel-path-status-word bits, the program should, prior to the initial use of the area, store zeros at the location where the channel-path-status word is to be stored.

## STORE CHANNEL REPORT WORD

STCRW	D <sub>2</sub> (B <sub>2</sub> )	[S]
'B239'	B <sub>2</sub>	D <sub>2</sub>

0

16 20

31

A CRW containing information affecting the channel subsystem is stored at the designated location.

The second-operand address is the logical address of the location where the CRW is to be stored and must be designated on a word boundary; otherwise, a specification exception is recognized.

When a malfunction or other condition affecting channel-subsystem operation is recognized, a channel report (consisting of one or more CRWs) describing the condition is made pending for retrieval and analysis by the program. The channel report contains information concerning the identity and state of a facility following the detection of the malfunction or other condition. For a description of the channel report, the CRW, and program-recovery actions related to the channel subsystem, see "Channel-Subsystem Recovery" on page 17-24.

When one or more channel reports are pending, the instruction causes a CRW to be stored at the designated location and condition code 0 to be set. A pending CRW can only be stored by the execution of STORE CHANNEL REPORT WORD and, once stored, is no longer pending. Thus, each pending CRW is presented only once to the program.

When no channel reports are pending in the channel subsystem execution of STORE CHANNEL REPORT WORD causes zeros to be stored at the designated location and condition code 1 to be set.

### Special Conditions

STORE CHANNEL REPORT WORD can encounter the program exceptions described or listed below.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of STORE CHANNEL REPORT WORD is suppressed on all addressing and protection exceptions.

### Resulting Condition Code:

- |   |              |
|---|--------------|
| 0 | CRW stored   |
| 1 | Zeros stored |
| 2 | —            |
| 3 | —            |

### Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification

#### Programming Notes:

1. CRW overflow conditions may occur if STORE CHANNEL REPORT WORD is not executed to clear pending channel reports. If the overflow condition is encountered, one or more channel-report words have been lost. (See "Channel-Subsystem Recovery" on page 17-24 for details.)
2. A pending CRW can be cleared by any CPU in the configuration executing STORE CHANNEL REPORT WORD, regardless of whether a machine-check interruption has occurred in any CPU.

## STORE SUBCHANNEL

STSCH	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B234'	B <sub>2</sub> D <sub>2</sub>

16      20      31

Control and status information for the designated subchannel is stored in the designated SCHIB.

General register 1 contains a subsystem-identification word that designates the subchannel for which the information is to be stored. The second-operand address is the logical address of the SCHIB and must be designated on a word boundary; otherwise, a specification exception is recognized.

When the extended-I/O-measurement-block facility is not installed, the information that is stored in the SCHIB consists of a path-management-control word, a SCSW, and three words of model-dependent information. When the extended-I/O-measurement-block facility is installed, the information that is stored in the SCHIB consists of a path-management-control word, a SCSW, the measurement-block-address field, and one word of model-dependent information. (See "Subchannel-Information Block" on page 15-1.)

The execution of STORE SUBCHANNEL does not change any information at the subchannel.

Condition code 0 is set to indicate that control and status information for the designated subchannel has been stored in the SCHIB. When the execution of

STORE SUBCHANNEL results in the setting of condition code 0, the information in the SCHIB indicates a consistent state of the subchannel.

#### Special Conditions

**Condition code 3** is set, and no other action is taken, when the designated subchannel is not operational for STORE SUBCHANNEL. A subchannel is not operational for STORE SUBCHANNEL if the subchannel is not provided in the channel subsystem.

STORE SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

#### Resulting Condition Code:

- 0 SCHIB stored
- 1 —
- 2 —
- 3 Not operational

#### Program Exceptions:

- Access (store, operand 2)
- Operand
- Privileged operation
- Specification

#### Programming Notes:

1. Device status that is stored in the SCSW may include device-busy, control-unit-busy, or control-unit-end indications.
2. The information that is stored in the SCHIB is obtained from the subchannel. The STORE SUBCHANNEL instruction does not cause the

channel subsystem to interrogate the addressed device.

3. STORE SUBCHANNEL may be executed at any time to sample conditions existing at the subchannel, without causing any pending status conditions to be cleared.
  4. Repeated execution of STORE SUBCHANNEL without an intervening delay (for example, to determine when a subchannel changes state) should be avoided because repeated accesses of the subchannel by the CPU may delay or prohibit access of the subchannel by a channel subsystem to update the subchannel.

# TEST PENDING INTERRUPTION

TPI	$D_2(B_2)$	[S]
0	'B236'	$B_2$

The I/O-interruption code for a pending I/O interruption at a subchannel is stored at the location designated by the second-operand address, and the pending I/O-interruption request is cleared.

The second-operand address, when nonzero, is the logical address of the location where the two-word I/O-interruption code, consisting of words 0 and 1, is to be stored. The second-operand address must be designated on a word boundary; otherwise, a specification exception is recognized.

If the second-operand address is zero, the three-word I/O-interruption code, consisting of words 0-2, is stored at real locations 184-195. In this case, low-address protection and key-controlled protection do not apply.

In the access-register mode when the second-operand address is zero, it is unpredictable whether access-register translation occurs for access register B<sub>2</sub>. If the translation occurs, the resulting address-space-control element is not used; that is, the interruption code still is stored at real locations 184-195.

Pending I/O-interruption requests are accepted only for those I/O-interruption subclasses allowed by the I/O-interruption-subclass mask in control register 6 of the CPU executing the instruction. If no I/O-interruption requests exist that are allowed by control register 6, the I/O-interruption code is not stored, the second-

operand location is not modified, and condition code 0 is set.

If a pending I/O-interruption request is accepted, the I/O-interruption code is stored, the pending I/O-interruption request is cleared, and condition code 1 is set. The I/O-interruption code that is stored is the same as would be stored if an I/O interruption had occurred. However, PSWs are not swapped as when an I/O-interruption occurs.

The I/O-interruption code that is stored during the execution of the instruction is defined as follows:

Word

0	Subsystem-Identification Word
1	Interruption Parameter
2	Interruption-Identification Word

#### **Subsystem-Identification Word (SID):**

Bits 32-63 of the SID are placed in word 0.

See “I/O-Instruction Formats” in Chapter 14.

**Interruption Parameter:** Word 1 contains a four-byte parameter that was specified by the program and passed to the subchannel in word 0 of the ORB or the PMCW. When a device presents alert status and the interruption parameter was not previously passed to the subchannel by an execution of START SUBCHANNEL or MODIFY SUBCHANNEL, this field contains zeros.

**Interruption-Identification Word:** Word 2, when stored, contains the interruption-identification word, which further identifies the source of the I/O-interruption. Word 2 is stored only when the second-operand address is zero.

The interruption-identification word is defined as follows:

**A bit (A):** Bit 0 of the interruption-identification word specifies the type of pending I/O-interruption request that was cleared. When bit 0 is zero, the I/O-interruption request was associated with a subchannel.

**I/O-Interruption Subclass (ISC):** Bit positions 2-4 of the interruption-identification word contain an unsigned binary integer, in the range 0-7, that specifies the I/O-interruption subclass associated with the subchannel for which the pending I/O-interruption request was cleared. The remaining bit positions are reserved and stored as zeros.

### Special Conditions

TEST PENDING INTERRUPTION can encounter the program exceptions described or listed below.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of TEST PENDING INTERRUPTION is suppressed on all addressing and protection exceptions.

### Resulting Condition Code:

- |   |                              |
|---|------------------------------|
| 0 | Interruption code not stored |
| 1 | Interruption code stored     |
| 2 | —                            |
| 3 | —                            |

### Program Exceptions:

- Access (store, operand 2, second-operand address nonzero only)
- Privileged operation
- Specification

### Programming Notes:

1. TEST PENDING INTERRUPTION should only be executed with a second-operand address of zero when I/O interruptions are masked off. Otherwise, an I/O-interruption code stored by the instruction may be lost if an I/O interruption occurs. The I/O-interruption code that identifies the source of an I/O interruption taken subsequent to TEST PENDING INTERRUPTION is also stored at real locations 184-195, replacing an I/O-interruption code that was stored by the instruction.
2. In the access-register mode when the second-operand address is zero, an access exception is recognized if access-register translation occurs and the access register is in error. This exception

can be prevented by making the  $B_2$  field zero or by placing 00000000 hex, 00000001 hex, or any other valid contents in the access register.

## TEST SUBCHANNEL

TSCH	D <sub>2</sub> (B <sub>2</sub> )	[S]
0	'B235'	B <sub>2</sub>

Control and status information for the subchannel is stored in the designated IRB.

General register 1 contains a subsystem-identification word that designates the subchannel for which the information is to be stored. The second-operand address is the logical address of the IRB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The information that is stored in the IRB consists of a SCSW, an extended-status word, and an extended-control word. (See “Interruption-Response Block” on page 16-6.)

If the subchannel is status pending, the status-pending bit of the status-control field is stored as one. Whether or not the subchannel is status pending has an effect on the functions that are performed when TEST SUBCHANNEL is executed.

When the subchannel is status pending and TEST SUBCHANNEL is executed, information, as described above, is stored in the IRB, followed by the clearing of certain conditions and indications that exist at the subchannel as described in Figure 14-2 on page 14-21. If an I/O-interruption request is pending for the subchannel, the request is cleared. Condition code 0 is set to indicate that these actions have been taken.

When the subchannel is not status pending and TEST SUBCHANNEL is executed, information (as described above) is stored in the IRB, and no conditions or indications are cleared. Condition code 1 is set to indicate that these actions have been taken.

Figure 14-2 on page 14-21 describes which conditions and indications are cleared by TEST SUBCHANNEL when the subchannel is status pending.

All other conditions and indications at the subchannel remain unchanged.

Field	Subchannel Conditions*				
	Alert Status Pdg	Int Status Pdg	Pri Status Pdg	Sec Status Pdg	Status Pdg Alone
Function Control	C	Nc	C	C	C
Activity Control	Cp	Nr	Cp	Cp	Cp
Status Control	Cs	Cs	Cs	Cs	Cs
N Condition	C	Nr	C	C	C

**Explanation:**

- \* Note that the rightmost column applies to status pending when it is alone. The other four status-pending conditions result in the clearing actions given. These actions apply both when a single status-pending condition occurs and when a combination of the four status-pending conditions occurs. In the combination case, all the clearing actions of the individual cases apply.

C	Cleared.
Cp	The resume-, start-, halt-, clear pending, and suspended conditions are cleared.
Cs	The status-pending condition is cleared.
Nc	Not changed unless function control indicates the halt function and activity control indicates suspended. If both the halt function and suspended are indicated, conditions are cleared as for status pending alone.
Nr	Not changed unless activity control indicates suspended and function control indicates the start function with or without the halt function. If the halt function is indicated, the conditions are cleared as for status pending alone. If only the start function is indicated, the resume-pending condition and the N condition are cleared.

Figure 14-2. Conditions and Indications Cleared at the Subchannel by TEST SUBCHANNEL

### Special Conditions

**Condition code 3** is set, and no other action is taken, when the subchannel is not operational for TEST SUBCHANNEL. A subchannel is not operational for TEST SUBCHANNEL if the subchannel is not provided, has no valid device number associated with it, or is not enabled.

TEST SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

When the execution of TEST SUBCHANNEL is terminated on addressing and protection exceptions, the state of the subchannel is not changed.

The priority of recognition of program exceptions for the instruction is shown in Figure 14-3 on page 14-21.

### Resulting Condition Code:

- 0 IRB stored; subchannel status pending
- 1 IRB stored; subchannel not status pending
- 2 —
- 3 Not operational

### Program Exceptions:

- Access (store, operand 2)
- Operand
- Privileged operation
- Specification

1.-7	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.A	Specification exception due to the address specified by the second operand not being on a word boundary.
8.B	Access exceptions for an access to the subchannel-status-word, extended-status-word, and extended-control-word sections of the IRB designated by the second operand.
8.C	Operand exception due to an invalid field in the subsystem-identification word specified in register 1.
8.D	Access exceptions for an access to the extended-measurement-word section of the IRB designated by the second operand when the extended-I/O-measurement-word mode is enabled at the designated subchannel.

Figure 14-3. Priority of Execution: TEST SUBCHANNEL

**Programming Notes:**

1. Device status that is stored in the SCSW may include device-busy, control-unit-busy, or control-unit-end indications.
2. The information that is stored in the IRB is obtained from the subchannel. The TEST SUBCHANNEL instruction does not cause the channel subsystem to interrogate the addressed device.
3. When an I/O interruption occurs, it is the result of a status-pending condition at the subchannel, and typically TEST SUBCHANNEL is executed to clear the status. TEST SUBCHANNEL may also be executed at any other time to sample conditions existing at the subchannel.
4. Repeated execution of TEST SUBCHANNEL to determine when a start function has been completed should be avoided because there are conditions under which the completion of the start function may or may not be indicated. For example, if the channel subsystem is holding an interface-control-check (IFCC) condition in abeyance (for any subchannel) because another subchannel is already status pending, and if the start function being tested by TEST SUBCHANNEL has as the only path available for selection the channel path with the IFCC condition, then the start function may not be initiated until the status-pending condition in the other subchannel is cleared, allowing the IFCC condition to be indicated at the subchannel to which it applies.
5. Repeated execution of TEST SUBCHANNEL without an intervening delay, for example, to determine when a subchannel changes state, should be avoided because repeated accesses of the subchannel by the CPU may delay or prohibit accessing of the subchannel by the channel subsystem. Execution of TEST SUBCHANNEL by multiple CPUs for the same subchannel at approximately the same time may have the same effect and also should be avoided.
6. The priority of I/O-interruption handling by a CPU can be modified by the execution of TEST SUBCHANNEL. When TEST SUBCHANNEL is executed and the designated subchannel has an I/O-interruption request pending, that I/O-interruption request is cleared, and the SCSW is stored, without regard to any previously established priority. The relative priority of the remaining I/O-interruption requests is unchanged.

Some I/O instructions specify to the channel subsystem that a function is to be performed. Collectively, these functions are referred to as the basic I/O functions. The basic I/O functions are the clear, halt, start, resume, and channel-path-reset functions.

## Control of Basic I/O Functions

Information that is present at the subchannel controls how the clear, halt, resume, and start functions are performed. This information is communicated to the program in the subchannel-information block during the execution of STORE SUBCHANNEL.

## Subchannel-Information Block

The subchannel-information block (SCHIB) is the operand of the MODIFY SUBCHANNEL and STORE SUBCHANNEL instructions. The two rightmost bits of the SCHIB address are zeros, designating the

SCHIB on a word boundary. The SCHIB contains three major fields: the path-management-control word (PMCW), the subchannel-status word (SCSW), and a model-dependent area. When the extended-I/O-measurement-block facility is installed the SCHIB also contains the measurement-block-address field. (Figure 15-1 on page 15-2 shows the format of the PMCW, and Figure 16-2 on page 16-7 shows the format of the SCSW.)

STORE SUBCHANNEL is used to store the current PMCW, the SCSW, model-dependent data, and, when the extended-I/O-measurement-block facility is installed, the measurement-block-address field, for the designated subchannel. MODIFY SUBCHANNEL alters certain PMCW fields and, when the extended-I/O-measurement-block facility is installed, the measurement-block address in the subchannel. When the program needs to change the contents of one or more of the PMCW fields, the normal procedure is to (1) issue STORE SUBCHANNEL to obtain the current contents, (2) perform the required modifications to the PMCW field or the measurement-block-

address field in main storage, and (3) issue MODIFY SUBCHANNEL to pass the new information to the subchannel. The SCHIB has the following format:

Word	
0	
1	
2	
3	Path-Management-Control Word
4	
5	
6	
7	
8	Subchannel-Status Word
9	
10	
11	Model-Dependent Area / Measurement-Block Address
12	Model-Dependent Area

## Path-Management-Control Word

Words 0-6 of the SCHIB contain the path-management-control word (PMCW). The PMCW has the format shown in Figure 15-1 on page 15-2 when the subchannel is valid (see “Device Number Valid (V)” on page 15-4).

The format of the PMCW is as follows:

Word	Interruption Parameter							
0	0 0	ISC	0 0 0	E	LM	MM	D	T/V
1	LPM		PNOM		LPUM		PIM	
2	MBI				POM		PAM	
3	CHPID-0		CHPID-1		CHPID-2		CHPID-3	
4	CHPID-4		CHPID-5		CHPID-6		CHPID-7	
5	0 0 0 0 0 0 0 0	0	0 0 0 0 0 0 0 0	0	0 0 0 0 0 0 0 0	0	0 0 0 0 0 0 0 0	F X S
6	0	2	5	8 9	11 13	16	24	29 31

Figure 15-1. PMCW Format

**Interruption Parameter:** Bit positions 0-31 of word 0 contain the interruption parameter that is stored as word 1 of the interruption code. The interruption parameter can be set to any value by START SUB-

CHANNEL and MODIFY SUBCHANNEL. The initial value of the interruption parameter is zero.

**I/O-Interruption-Subclass Code (ISC):** Bits 2-4 of word 1 are an unsigned binary integer, in the range 0-7, that corresponds to the bit position of the I/O-interruption subclass-mask bit in control register 6 of each CPU in the configuration. The setting of that mask bit in control register 6 of a CPU controls the recognition of interruption requests relating to this subchannel by that CPU (see “Priority of Interruptions” on page 16-4). The ISC can be set to any value by MODIFY SUBCHANNEL. The initial value of the ISC is zero.

**Reserved:** Bits 0, 1, and 5-7 of word 1 are reserved and stored as zeros by STORE SUBCHANNEL. Bits 0, 1, 6, and 7 must be zeros when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized. Bit 5 of word 1 is ignored when MODIFY SUBCHANNEL is executed.

**Enabled (E):** Bit 8 of word 1, when one, indicates that the subchannel is enabled for all I/O functions. When the E bit is zero, status presented by the device is not made available to the program, and I/O instructions other than MODIFY SUBCHANNEL and STORE SUBCHANNEL that are executed for the designated subchannel cause condition code 3 to be set. The E bit can be either zero or one when MODIFY SUBCHANNEL is executed; initially, all subchannels are not enabled; IPL causes the IPL I/O device to become enabled.

**Limit Mode (LM):** When the address-limit-checking facility is installed, bits 9 and 10 of word 1 define the limit mode (LM) of the subchannel. The limit mode is used by the channel subsystem when address-limit checking is invoked for an I/O operation. (See “Address-Limit Checking” on page 17-22.) Address-limit checking is under the control of the address-limit-checking-control bit that is passed to the subchannel in the operation-request block (ORB) during the execution of START SUBCHANNEL. (See “Address-Limit-Checking Control (A)” on

page 15-24.) The definitions of the LM bits, whose values are used during data transfer, are as follows:

<b>Bit 9</b>	<b>Bit 10</b>	<b>Function</b>
0	0	Initialized value. No limit checking is performed for this subchannel.
0	1	Data address must be equal to or greater than the current address limit.
1	0	Data address must be less than the current address limit.
1	1	Reserved.

Bit positions 9 and 10 can contain any of the first three bit combinations shown above when MODIFY SUBCHANNEL is executed. Specification of the reserved bit combination in the operand causes an operand exception to be recognized when MODIFY SUBCHANNEL is executed.

When the address-limit-checking facility is not installed, bits 9-10 of word 1 may be set as described above; however, they are ignored and are not set at the specified subchannel. When bits 9-10 are not specified as described above and MODIFY SUBCHANNEL is executed, an operand exception is recognized.

**Measurement-Mode Enable (MM):** Bits 11 and 12 of word 1 enable the measurement-block-update mode and the device-connect-time-measurement mode, respectively, of the subchannel. These bits can have any value when MODIFY SUBCHANNEL is executed; initially, neither measurement mode is

enabled. The definition of each of these bits is as follows:

<b>Bit 11</b>	<b>Measurement-Block-Update Enable:</b>
0	Initialized value. The subchannel is not enabled for measurement-block update. Storing of measurement-block data does not occur.
1	The subchannel is enabled for measurement-block update. If the measurement-block-update mode is active, measurement data is accumulated in the measurement block at the time channel-program execution is completed or suspended at the subchannel or completed at the device, as appropriate, provided no error conditions described by subchannel logout have been detected. (See "Measurement-Block Update" on page 17-2.) If the measurement-block-update mode is inactive, no measurement-block data is stored.
<b>Bit 12</b>	<b>Device-Connect-Time-Measurement Enable:</b>
0	Initialized value. The subchannel is not enabled for device-connect-time measurement. Storing of the device-connect-time interval (DCTI) in the extended-status word (ESW) does not occur.
1	The subchannel is enabled for device-connect-time measurement. If the device-connect-time-measurement mode is active and timing facilities are provided for the subchannel, the value of the DCTI is stored in the ESW when TEST SUBCHANNEL is executed after channel-program execution is completed or suspended at the subchannel, provided no error conditions described by subchannel logout have been detected. If the device-connect-time-measurement mode is inactive, no measurement values are stored in the ESW.

The meaning of the measurement-mode-enable bits (MM), described above, applies when the timing-facility bit for the subchannel is one. When the timing-facility bit is zero, the effect of the MM bits is changed, as described below under "Timing Facility." (For more discussion on measurement modes, see "Measurement-Block Update" on page 17-2 and "Device-Connect-Time Measurement" on page 17-9.)

**Multipath Mode (D):** Bit 13 of word 1, when one, indicates that the subchannel operates in the multipath mode when performing an I/O operation or chain of I/O operations. For proper operation in the multipath mode when more than one channel path is available for selection, the associated device must have the dynamic-reconnection feature installed and must be set up for multipath-mode operation. During performance of a start function in the multipath mode, a device is allowed to request service from the channel subsystem over any of the channel paths indicated at the subchannel as being available for selection (see “Logical-Path Mask (LPM)” on page 15-4 and “Path-Available Mask (PAM)” on page 15-7). Bit 13, when zero, indicates that the subchannel operates in single-path mode when performing an I/O operation or chain of I/O operations. In the single-path mode, the entire start function is performed by using the channel path on which the first command of the I/O operation or chain of I/O operations was accepted by the device. The D bit can be either zero or one when MODIFY SUBCHANNEL is executed; initially, the subchannel is in the single-path mode.

**Timing Facility (T):** Bit 14 of word 1, when one, indicates that the channel-subsystem-timing facility is available for the subchannel and is under the control of the two measurement-mode-enable bits (MM) and SET CHANNEL MONITOR. Bit 14, when zero, indicates that the channel-subsystem-timing facility is not available for the subchannel. When bit 14 is zero, the START SUBCHANNEL count is the only measurement data that can be accumulated in the measurement block for the subchannel. Storing of the START SUBCHANNEL count is under the control of bit 11 and SET CHANNEL MONITOR, as described above under “Measurement Mode Enable.” Similarly, if the T bit is zero, no device-connect-time-interval (DCTI) values can be measured for the subchannel. (See “Measurement-Block Update” on page 17-2 and “Device-Connect-Time Measurement” on page 17-9.)

**Device Number Valid (V):** Bit 15 of word 1, when one, indicates that the device-number field (see below) contains a valid device number and that a device associated with this subchannel may be physically installed. Bit 15, when zero, indicates that the subchannel is not valid, there is no I/O device currently associated with the subchannel, and the contents of all other defined fields of the SCHIB are unpredictable.

**Device Number:** Bit positions 16-31 of word 1 contain the binary representation of the four-digit hexadecimal device number of the device that is associated with this subchannel. The device number is a system-unique parameter that is assigned to the subchannel and the associated device when the device is installed.

**Logical-Path Mask (LPM):** Bits 0-7 of word 2 indicate the logical availability of channel paths to the associated device. Each bit of the LPM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A bit set to one means that the corresponding channel path is logically available; a zero means the corresponding channel path is logically not available. When a channel path is logically not available, the channel subsystem does not use that channel path to initiate performance of any clear, halt, resume, or start function, except when a dedicated allegiance exists for that channel path. When a dedicated allegiance exists at the subchannel for a channel path, the logical availability of the channel path is ignored whenever a clear, halt, resume, or start function is performed. (See “Channel-Path Allegiance” on page 15-11). If the subchannel is idle, the logical availability of the channel path is ignored whenever the control unit initiates a request to present alert status to the channel subsystem. The logical availability of a channel path associated with the subchannel can be changed by setting the corresponding LPM bit in the SCHIB and then issuing MODIFY SUBCHANNEL, or by setting the corresponding LPM bit in the ORB and then issuing START SUBCHANNEL. Initially, each installed channel path is logically available.

**Path-Not-Operational Mask (PNOM):** Any of bits 8-15 of word 2, when one, indicates that a path-not-operational condition has been recognized on the corresponding channel path. Each bit of the PNOM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. The channel subsystem recognizes a path-not-operational condition when, during an attempted device selection in order to perform a clear, halt, resume, or start function, the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel. When a path-not-operational condition is recognized, the state of the channel path changes from operational for the subchannel to not operational for the subchannel. A channel path is operational for the subchannel if the associated device appeared opera-

tional on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A device appears to be operational on a channel path when the device responds to an attempted device selection. A channel path is not operational for the subchannel if the associated device appeared not operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. Any of bits 8-15 of word 2, when zero, indicates that a path-not-operational condition has not been recognized on the corresponding channel path.

Initially, each of the eight possible channel paths associated with each subchannel is considered to be operational, regardless of whether the respective channel paths are installed or available; therefore, unless a path-not-operational condition is recognized during initial program loading, the PMCW, if stored, contains a PNOM of all zeros if stored prior to the execution of a CLEAR SUBCHANNEL, HALT SUBCHANNEL, RESUME SUBCHANNEL, or START SUBCHANNEL instruction.

**Programming Note:** The PNOM indicates those channel paths for which a path-not-operational condition has been recognized during the performance of the most recent clear, halt, resume, or start function. That is, the PNOM indicates which of the channel paths associated with the subchannel have made a transition from the operational to the not-operational state for the subchannel during the performance of the most recent clear, halt, resume, or start function. However, the transition of a channel path from the not-operational to the operational state for the subchannel is indicated in the POM. Therefore, the POM must be examined in order to determine whether any of the channel paths that are associated with a designated subchannel are operational for the subchannel.

Furthermore, while performing either a start function or a resume function, the transition of a channel path from the not-operational to the operational state for the subchannel is recognized by the channel subsystem only during the initiation sequence for the first command specified by the start function or implied by the resume function. Therefore, a channel path that is currently not operational for the subchannel can be used by the device associated with the subchannel when reconnecting to the channel subsystem in order to continue command chaining; however, the channel subsystem does not indicate a transition of

that channel path from the not-operational to the operational state for the subchannel in the POM.

POM Value and Device State before Selection Attempt		Value of Specified Bit Subsequent to Selection Attempt		
Device State <sup>1</sup>	POM	POM	PNOM <sup>2</sup>	SCSW N Bit
OP	0	1	0	0
NOP	0	0	0	0
OP	1	1	0	0
NOP	1	0	1	1 <sup>3</sup>

**Explanation:**

<sup>1</sup> Device state as it appears on the corresponding channel path.  
<sup>2</sup> Prior to the attempted device selection during the performance of either a start function or a resume function while the subchannel is suspended, the channel subsystem clears all existing path-not-operational conditions, if any, at the designated subchannel.  
<sup>3</sup> The N bit (bit 15 of word 0 of the SCSW) is indicated to the program and the N condition is cleared at the subchannel when TEST SUBCHANNEL is executed the next time the subchannel is status pending for other than intermediate status alone provided that it is not also suspended.

Figure 15-2. Resulting POM, PNOM, and N-Bit Values Subsequent to Selection Attempt

**Last-Path-Used Mask (LPUM):** Bits 16-23 of word 2 indicate the channel path that was last used for communicating or transferring information between the channel subsystem and the device. Each bit of the LPUM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. Each bit of the LPUM is stored as zero, except for the bit that corresponds to the channel path last used, whenever one of the following occurs:

1. The first command of a start or resume function is accepted by the device (see “Activity Control (AC)” on page 16-13).
2. The device and channel subsystem are actively communicating when the suspend function is performed for the channel program in execution.
3. Status has been accepted from the device and is recognized as an interruption condition, or a condition has been recognized that suppresses com-

mand chaining (see “*Interruption Conditions*” on page 16-1).

4. An interface-control-check condition has been recognized (see “*Interface-Control Check*” on page 16-28), and no subchannel-logout information is currently present in the subchannel.

The LPUM field of the PMCW contains the most recent setting. The initial value of the LPUM is zero.

**Path-Installed Mask (PIM):** Bits 24-31 of word 2 indicate which of the channel paths 0-7 to the I/O device are physically installed. The PIM indicates the validity of the channel-path identifiers (see below) for those channel paths that are physically installed. Each bit of the PIM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A PIM bit stored as one indicates that the corresponding channel path is installed. A PIM bit stored as zero indicates that the corresponding channel path is not installed. The PIM always reflects the full complement of installed paths to the device, regardless of how the system is configured. Therefore, some of the channel paths indicated in the PIM may not be physically available in that configuration, as indicated by the bit settings in the path-available mask (see below). The initial value of the PIM indicates all the physically installed channel paths to the device.

**Measurement-Block Index (MBI):** Bits 0-15 of word 3 form an index value used by the measurement-block-update facility when the measurement-block-update mode is active (see “*SET CHANNEL MONITOR*” on page 14-13.) and the subchannel is enabled for the mode (see “*Measurement-Mode Enable (MM)*” on page 15-3).

When the measurement-block index is used, five zero bits are appended on the right, and the result is added to the measurement-block-origin address designated by SET CHANNEL MONITOR. The calculated address, called the measurement-block address, designates the beginning of a 32-byte storage area where measurement data is stored. (See “*Measurement Block*” on page 17-3.) The MBI can contain any value when MODIFY SUBCHANNEL is executed; the initial value is zero.

**Programming Note:** The measurement-block-origin address specified by SET CHANNEL MONITOR is used as the origin address for the measurement blocks for subchannels in all subchannel sets avail-

able to the program. However, the two-byte measurement-block-index field is capable of supporting a maximum of 65,536 unique MBI values. It is the responsibility of the program to coordinate use of the measurement-block index among subchannels and subchannel sets.

**Path-Operational Mask (POM):** Bits 16-23 of word 3 indicate the last known operational state of the device on the corresponding channel paths. Each bit of the POM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. If the associated device appeared operational on a channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function, then the channel path is operational for the subchannel, and the bit corresponding to the channel path in the POM is one. A device appears to be operational on a channel path when the device responds to an attempted device selection. A channel path is also operational for the subchannel if MODIFY SUBCHANNEL is executed and the bit corresponding to that channel path in the POM is specified as one.

If the associated device appeared not operational on a channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function, then the channel path is not operational for the subchannel, and the bit corresponding to the channel path in the POM is zero. A channel path is also not operational for the subchannel if MODIFY SUBCHANNEL is executed and the bit corresponding to that channel path in the POM is specified as zero.

If the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel during an attempted device selection in order to perform a clear, halt, resume, or start function, then the channel subsystem recognizes a path-not-operational condition. If an SCSW is subsequently stored, then bit 15 of word 0 is one, indicating the path-not-operational condition. When a path-not-operational condition is recognized, the state of the channel path changes from operational for the subchannel to not operational for the subchannel.

When the channel path is not operational for the subchannel, a path-not-operational condition cannot be recognized. Moreover, a channel path that is not operational for the subchannel may be available for selection; if the channel subsystem chooses that

channel path while performing a path-management operation, and if, during the attempted device selection, the device appears to be operational again on that channel path, then the state of the channel path changes from not operational for the subchannel to operational for the subchannel.

The POM can contain any value when MODIFY SUBCHANNEL is executed. Initially, each of the eight possible channel paths associated with each subchannel is considered to be operational, regardless of whether the respective channel paths are installed or available; therefore, unless a path-not-operational condition is recognized during initial program loading, the PMCW, if stored, contains a POM of all ones if stored prior to the execution of a CLEAR SUBCHANNEL, HALT SUBCHANNEL, RESUME SUBCHANNEL, or START SUBCHANNEL instruction.

**Path-Available Mask (PAM):** Bits 24-31 of word 3 indicate the physical availability of installed channel paths. Each bit of the PAM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A PAM bit of one indicates that the corresponding channel path is physically available for use in accessing the device. A PAM bit of zero indicates the channel path is not physically available for use in accessing the device. When a channel path is not physically available, it may, depending on the model and the extent of failure, be used during performance of the reset-channel-path function. A channel path that is physically available may become not physically available as a result of reconfiguring the system, or this may occur as a result of the performance of the channel-path-reset function. The initial value of the PAM reflects the set of channel paths by which the I/O device is physically accessible at the time of initialization.

**Note:** The change in the availability of a channel path affects all subchannels having access to that channel path. Whenever the setting of a PAM bit is referred to in conjunction with the availability status of a channel path, for brevity, reference is made in this chapter to a single PAM bit instead of to the respective PAM bits in all of the affected subchannels.

**Channel-Path Identifiers (CHPIIDs):** Words 4 and 5 contain eight one-byte channel-path identifiers corresponding to channel paths 0-7 of the PIM. A CHPID is valid if the corresponding PIM bit is one. Each valid CHPID contains the identifier of a physical channel path to a control unit by which the associ-

ated I/O device may be accessed. A unique CHPID is assigned to each physical channel path in the system.

Different devices that are accessible by the same physical channel path have, in their respective subchannels, the same CHPID value. The CHPID value may, however, appear in each subchannel in different locations in the CHPID fields 0-7.

Subchannels that share an identical set of channel paths have the same corresponding PIM bits set to ones. The channel-path identifiers (CHPIIDs) for these channel paths are the same and occupy the same respective locations in each SCHIB.

**Reserved:** Bits 0-28 of word 6 are reserved and are stored as zeros by STORE SUBCHANNEL. They must be zeros when MODIFY SUBCHANNEL is executed; otherwise, an operand exception may be recognized.

**Measurement Block Format Control (F):** When the extended-measurement-block facility is installed, bit 29 of word 6 specifies the format of the measurement block to be stored when the subchannel is enabled for the measurement-block-update mode, and measurement-block-update mode is active. The bit can contain any value when MODIFY SUBCHANNEL is executed. The initial value is zero. The definition of the bit is as follows:

Bit	Measurement-Block-Format Control:
29	<b>Measurement-Block-Format Control:</b>
0	Format-0 measurement block. Specifies that a format-0 measurement block is used when performing a measurement-block update for the subchannel. The address of the 32-byte measurement block is obtained using the MBI provided by MSCH in conjunction with the MBO provided by SCHM.
1	Format-1 measurement block. Specifies that a format-1 measurement block is used when performing a measurement-block update for the subchannel. The address of the 64-byte format-1 measurement block is provided by MSCH.

If the extended-measurement-block facility is not installed, bit 29 of word 6 of the SCHIB operand must

be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

**Extended Measurement Word Mode Enable (X):**

When the extended-measurement-word facility is installed and enabled, bit 30 of word 6 enables the extended-measurement-word mode for the subchannel. Initially, the extended-measurement-word mode is not enabled. The definition of the bit is as follows:

Bit	Measurement-Block-Word-Mode Enable:
30	<b>Measurement-Block-Word-Mode Enable:</b>
0	Initialized value. The subchannel is not enabled for extended-measurement-word mode. Storing of the extended-measurement word does not occur.
1	The subchannel is enabled for extended-measurement-word mode. Measurement data is stored in the extended-measurement word at the time channel-program execution is completed or suspended at the subchannel or completed at the device, as appropriate, provided no error conditions described by subchannel logout have been detected.

If the extended-measurement-word facility is not installed, or is installed but is not enabled, bit 30 of word 6 of the SCHIB operand must be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

**Concurrent Sense (S):** Bit 31 of word 6, when one, indicates that the subchannel is in the concurrent-sense mode. When the subchannel is in concurrent-sense mode, whenever the subchannel becomes status pending with alert status, and the status byte accepted from the device contains the unit-check indication, then the channel subsystem may attempt to retrieve sense information from the associated device and place that sense information in the extended-control word.

If the concurrent-sense facility is not installed, bit 31 of word 6 of the SCHIB operand must be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

**Subchannel-Status Word**

Words 7-9 of the SCHIB contain a copy of the SCSW. The format of the SCSW is described in "Subchannel-Status Word" on page 16-6. The SCSW is stored by the execution of either STORE SUBCHANNEL or TEST SUBCHANNEL (see "STORE SUBCHANNEL" on page 14-18 and "TEST SUBCHANNEL" on page 14-20).

**Model-Dependent Area/Measurement Block Address**

When the extended-I/O-measurement-block facility is not installed, words 10-12 of the SCHIB contain model-dependent information.

When the extended-I/O-measurement-block facility is installed, words 10-11 are defined as the measurement-block-address field. Word 12 contains model-dependent information.

When (1) the measurement-block-update mode is active (see "SET CHANNEL MONITOR" on page 14-13), (2) the subchannel is enabled for the mode (see "Measurement-Mode Enable (MM)" on page 15-3), and (3) the format-1-measurement block is specified (see "Measurement Block Format Control (F)" on page 15-7) at the subchannel, the measurement-block-address field contains the absolute storage address of the measurement block used by the measurement-block-update facility. The measurement-block address designates the beginning of a 64-byte storage area and must be designated on 64-byte boundary. The initial value of the measurement block address is zero.

## Summary of Modifiable Fields

\*Figure 15-3 on page 15-9 lists the initial settings for fields in a subchannel whose device-number-valid bit is one and indicates what modifies the fields.

All of the PMCW fields contain meaningful information when STORE SUBCHANNEL is executed and the designated subchannel is idle. Subchannel fields that the channel subsystem does not modify contain

valid information whenever STORE SUBCHANNEL is executed, provided that the device-number-valid bit is one. The validity of the subchannel fields that are modifiable by the channel subsystem depends on the state of the subchannel at the time STORE SUBCHANNEL is executed.

Subchannel Field	Initial Value <sup>1</sup>	Program Modifies by Executing	Modified by Channel Subsystem <sup>2</sup>
Interruption parameter	Zeros	MSCH,SSCH	No
I/O-interruption-subclass code	Zeros	MSCH	No
Enabled (E)	Zero	MSCH	No
Limit mode (M)	Zeros	MSCH <sup>7</sup>	No
Measurement mode (MM)	Zeros	MSCH	Yes <sup>3</sup>
Multipath mode (D)	Zero	MSCH	No
Timing facility (T)	Installed value <sup>4</sup>	None	No
Device number valid (V)	Installed value <sup>4</sup>	None	No
Device number	Installed value <sup>4</sup>	None	No
Logical-path mask (LPM)	Path-installed-mask value	MSCH,SSCH	No
Path-not-operational mask (PNOM)	Zeros	CSCH,SSCH,RSCH <sup>5</sup>	Yes
Last-path-used mask (LPUM)	Zeros	CSCH	Yes
Path-installed mask (PIM)	Installed value <sup>4</sup>	None	No
Measurement-block index (MBI)	Zeros	MSCH	No
Path-operational mask (POM)	Ones	CSCH,MSCH,RSCH <sup>5</sup>	Yes
Path-available mask (PAM)	Installed values <sup>4,6</sup>	None	Yes <sup>6</sup>
Channel-path ID 0-7	Installed value <sub>4</sub>	None	No
Concurrent sense (S)	ZERO	MSCH	No
Subchannel-status word (SCSW)	Zero	TSCH	Yes
Model-dependent area	*	None	*
Measurement-block-format control (F)	Zero	MSCH	No
Extended-measurement-word enable (X)	Zero	MSCH	No
Measurement-block address	Zeros	MSCH	No

Figure 15-3. Modification of Subchannel Fields (Part 1 of 2)

**Explanation:**

- \* Model dependent.
- 1 These fields are not meaningful if the subchannel is not valid. Initialization of a subchannel is performed when I/O-system reset occurs. (See the section "I/O-System Reset" in Chapter 17, "I/O Support Functions.") One or more of the installed-value parameters that are unmodifiable by the program may be set when the subchannel is idle. In this case, all the program-modifiable fields are set to their initialized values, and the program is notified of such a change by a channel report. (See the section "Channel-Report Word" in Chapter 17, "I/O Support Functions.")
- 2 Subchannel fields that are not normally modifiable by the channel subsystem may be modified as a result of dynamic configuration changes or as a result of external actions. When this occurs, the program is notified of the change by a channel report that is made pending at the time of the change.
- 3 When any of the following error conditions associated with the measurement-block-update mode is detected, the measurement-block-update mode is disabled by the channel subsystem (bit 11 of word 1 of the SCHIB is zero) in the affected subchannel. The device-connect-time-measurement-enable bit (bit 12 of word 1 of the SCHIB) is never modified by the channel subsystem.
  - Measurement program check
  - Measurement protection check
  - Measurement data check
  - Measurement key check
- 4 This information is entered when the channel-subsystem configuration is established
- 5 The mask is modified by the resume function only when the subchannel is in the suspended state at the time RESUME SUBCHANNEL is executed.
- 6 The channel subsystem may modify the PAM to reflect changes in the system configuration caused by partitioning or unpartitioning channel paths because of reconfiguration or permanent failure of part of the I/O system.

Figure 15-3. Modification of Subchannel Fields (Part 2 of 2)

**Programming Notes:**

1. System performance may be degraded if the LPM is not used to make channel paths for which a path-not-operational condition has been indicated in the PNOM logically not available.
2. If, during the performance of a start function, a channel path becomes not physically available because a channel-path failure has been recognized, continued performance of the start function may be precluded. That is, the program may or may not be notified, and the subchannel may remain in the subchannel-and-device-active state until cleared by the performance of the clear function.
3. If the same MBI is placed in more than one subchannel by the program, the channel-subsystem-monitoring facility updates the same locations with measurement data relating to more than one subchannel. In this case, the values stored in the measurement data are unpredictable. (See "Measurement-Block Update" on page 17-2.)
4. Modification of the I/O configuration (reconfiguration) may be accomplished in various ways depending on the model. If the reconfiguration

procedure affects the physical availability of a channel path, then any change in availability can be detected by executing STORE SUBCHANNEL for a subchannel that has access to the channel path and by subsequently examining the PAM bits of the SCHIB.

5. The definitions of the PNOM, POM, and N bit are such that a path-not-operational condition is reported to the program only the first time the condition is detected by the channel subsystem after the corresponding POM bit is set to one.

For example, if the POM bit for every channel path available for selection is one and the device appears not operational on all corresponding channel paths while the channel subsystem is attempting to initiate a start function at the device, the channel subsystem makes the subchannel status pending, with deferred condition code 3 and with the N bit stored as one. The PNOM in the SCHIB indicates the channel path or channel paths that appeared not operational, for which the corresponding POM bits have been set to zeros. The next START SUBCHANNEL causes the channel subsystem to again attempt device selection by choosing a channel path from among all of the channel paths that are available

for selection. If device selection is not successful and all channel paths available for selection have again been chosen, deferred condition code 3 is set, but the N bit in the SCSW is zero. The POM contains zeros in at least those bit positions that correspond to the channel paths that are available for selection. (See “Channel-Path Availability” on page 15-12 for a description of the term “available for selection.”) When the N bit in the SCSW is zero, the PNOM is also zero.

6. If the program is to detect path-not-operational conditions, the PNOM should be inspected following the execution of TEST SUBCHANNEL (which results in the setting of condition code zero and the valid storing of the N bit as one) and preceding the performance of another start, resume, halt, or clear function at the subchannel.

established, the channel subsystem maintains the working allegiance at the subchannel for the channel path until either the subchannel is no longer device active or a dedicated allegiance is recognized, whichever occurs earlier. Unless a dedicated allegiance is recognized, a working allegiance for a channel path is extended to the set of channel paths that are available for selection if the device is specified to be operating in the multipath mode (that is, the multipath-mode bit is stored as one in the SCHIB). Otherwise, the working allegiance remains only for that channel path over which the start function was initiated.

Once a working allegiance is established for a channel path or set of channel paths, the working allegiance is not changed until the subchannel is no longer device active or until a dedicated allegiance is established. If the subchannel is operating in the single-path mode, a working allegiance is maintained only for a single path.

While a working allegiance exists at a subchannel, an active allegiance can occur only for a channel path for which the working allegiance is being maintained, unless the device is specified as operating in the multipath mode. When the device is specified as operating in the multipath mode, an active allegiance may also occur for a channel path that is not available for selection if the presentation of status by the device on that channel path causes an alert interruption condition to be recognized.

A working allegiance is cleared in any subchannel having access to a channel path if the channel path becomes not physically available.

## Active Allegiance

A subchannel has an active allegiance established for a channel path no later than when active communication has been initiated on that channel path with an I/O device. The subchannel can have an active allegiance to only one channel path at a time. While the subchannel has an active allegiance for a channel path, the channel subsystem does not actively communicate with that device on any other channel path. When the channel subsystem accepts a no-longer-busy indication from the device that does not cause an interruption condition, this status does not constitute the initiation of active communication. An active allegiance at a subchannel for a channel path is terminated when the channel subsystem is no

---

## Channel-Path Allegiance

The channel subsystem establishes allegiance conditions between subchannels and channel paths. The kind of allegiance established at a subchannel for a channel path or set of channel paths depends upon the state of the subchannel, the device, and the information, if any, transferred between the channel subsystem and device. The way in which path management is handled during the performance of a clear, halt, resume, or start function is determined by the kind of allegiance, if any, currently recognized between a subchannel and a channel path.

Performing the clear function at a subchannel clears any currently existing allegiance condition in the subchannel for all channel paths.

Performing the reset-channel-path function clears all currently existing allegiances for that channel path in all subchannels.

When a channel path becomes not physically available, all internal indications of prior allegiance conditions are cleared in all subchannels having access to the designated channel path.

## Working Allegiance

A subchannel has a working allegiance for a channel path when the subchannel becomes device active on that channel path. Once a working allegiance is

longer actively communicating with the I/O device on that channel path.

A working allegiance can become an active allegiance.

## Dedicated Allegiance

If a channel path is physically available (that is, if the corresponding PAM bit is one), a dedicated allegiance may be recognized for that channel path. If a channel path is not physically available, a dedicated allegiance cannot be recognized for the corresponding channel path. The channel subsystem establishes a dedicated allegiance at the subchannel for a channel path when (1) the subchannel becomes status pending with alert status, and device status containing the unit-check indication is present but (2) concurrent-sense information is not present at the subchannel. A dedicated allegiance is maintained until the subchannel is no longer start pending (unless it becomes suspended) or resume pending following performance of the next start function, clear function, or channel-path-reset function or the next resume function if applicable. If the subchannel becomes suspended, the dedicated allegiance remains until the resume function is initiated and the subchannel is no longer resume pending. Unless a clear or channel-path-reset function is performed, the subchannel establishes a working allegiance when the dedicated allegiance ends. This occurs when the subchannel becomes device active. While a dedicated allegiance exists at a subchannel for a channel path, only that channel path is available for selection until the dedicated-allegiance condition is cleared.

A dedicated allegiance can become an active allegiance. While a dedicated allegiance exists, an active allegiance can only occur for the same channel path.

A currently existing dedicated allegiance is cleared at any subchannel having access to a channel path when the channel path becomes not physically available or whenever the device appears not operational

on the channel path for which the dedicated allegiance exists.

## Channel-Path Availability

When a channel path is not physically available, the channel subsystem does not use the channel path to perform any of the basic I/O functions except, in some cases, the channel-path-reset function and does not respond to any control-unit-initiated requests on that same channel path. If a channel path is not physically available, the condition is indicated by the corresponding path-available-mask PAM bit being zero when STORE SUBCHANNEL is executed (see “Path-Available Mask (PAM)” on page 15-7). Furthermore, if the channel path is not physically available for the subchannel designated by STORE SUBCHANNEL, then it is not physically available for any subchannel that has a device which is accessible by that channel path.

Unless a dedicated allegiance exists at a subchannel for the channel path, a channel path becomes available for selection if it is logically available and physically available, as indicated by the bits in the LPM and PAM corresponding to the channel path being stored as ones when STORE SUBCHANNEL is executed. If a dedicated allegiance exists at a subchannel for the channel path, only that channel path is available for selection, and the setting of the corresponding LPM bit is ignored. If the channel path is currently being used and a dedicated allegiance exists at the subchannel for the channel path, selection of the device is delayed until the channel path is no longer being used.

The availability status of the eight logical paths to the associated device described in Figure 15-4 on page 15-13 is determined by the hierarchical arrangement of the corresponding bit values contained in the PIM, PAM, and LPM and by existing conditions, if any, recognized by the channel subsystem.

## Clear-Function Path Management

Value of Bit 'n'			Channel-Path Condition1	Channel-Path State
PIM	PAM	LPM		
0	$0^2$	-	X	Not installed
1	0	-	X	Not physically available
1	1	$0^3$	X	Not logically available
1	1	$1^3$	Active	Available for selection <sup>4</sup>
1	1	1	Inactive	Available for selection

**Explanation:**

- Bit value is not meaningful.
- <sup>1</sup> If the channel path is recognized as being used in active communication with a device, the channel-path condition is described as active. Otherwise, its condition is described as inactive.
- <sup>2</sup> A PAM bit cannot have the value one when the corresponding PIM bit has the value zero.
- <sup>3</sup> If a dedicated allegiance exists to the channel path at the subchannel, the state of the bit is ignored, and the channel path is considered to be available for selection.
- <sup>4</sup> The channel path may appear to be active when a channel-path-terminal condition has been recognized.
- X Condition is not meaningful!

Figure 15-4. Path condition and Path-Availability Status for PIM, PAM, and LPM Values

## Control-Unit Type

In “Clear Function” on page 15-13, “Halt Function” on page 15-15, and “Start Function and Resume Function” on page 15-18, reference is made to type-1, type-2, and type-3 control units. For a description of these control-unit types, see the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974. For the purposes of this definition, all control units attaching to a serial-I/O interface are considered type-2 control units.

---

## Clear Function

Subsequent to the execution of CLEAR SUBCHANNEL, the channel subsystem performs the clear function. Performance of the clear function consists in (1) performing a path-management operation, (2) modifying fields at the subchannel, (3) issuing the clear signal to the associated device, and (4) causing the subchannel to be made status pending, indicating the completion of the clear function.

A path-management operation is performed as part of the clear function in order to examine channel-path conditions for the associated subchannel and to attempt to choose an available channel path on which the clear signal can be issued to the associated device.

Channel-path conditions are examined in the following order:

1. If the channel subsystem is actively communicating or attempting to establish active communication with the device to be signaled, the channel path that is in use is chosen.
2. If the channel subsystem is in the process of accepting a no-longer-busy indication (which will not cause an interruption condition to be recognized) from the device to be signaled, and the associated subchannel has no allegiance to any channel path, the channel path that is in use is chosen.
3. If the associated subchannel has a dedicated allegiance for a channel path, that channel path is chosen.
4. If the associated subchannel has a working allegiance for one or more channel paths, one of those channel paths is chosen.
5. If the associated subchannel has no allegiance for any channel path, if a last-used channel path is indicated, and if that channel path is available for selection, that channel path is chosen. If that channel path is not available for selection, either no channel path is chosen or a channel path is chosen from the set of channel paths, if any, that are available for selection (as though no last-used channel path were indicated).
6. If the associated subchannel has no allegiance for any channel path, if no last-used channel path is indicated, and if there exist one or more channel paths that are available for selection, one of those channel paths is chosen.

If none of the channel-path conditions listed above apply, no channel path is chosen.

For item 4, for item 5 under the specified conditions, and for item 6, the channel subsystem chooses a channel path from a set of channel paths. In these

cases, the channel subsystem may attempt to choose a channel path, provided that the following conditions *do not* apply:

1. A channel-path-terminal condition exists for the channel path.
2. Another subchannel has an active allegiance for the channel path.
3. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.
4. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

## Clear-Function Subchannel Modification

Path-management-control indications at the subchannel are modified during performance of the clear function. Effectively, this modification occurs after the attempt to choose a channel path, but prior to the attempt to select the device to issue the clear signal. The path-management-control indications that are modified are as follows:

1. The state of all eight possible channel paths at the subchannel is set to operational for the subchannel.
2. The last-path-used indication is reset to indicate no last-used channel path.
3. Path-not-operational conditions, if any, are reset.

## Clear-Function Signaling and Completion

Subsequent to the attempt to choose a channel path and the modification of the path-management-control fields, the channel subsystem, if conditions allow, attempts to select the device to issue the clear signal. (See “Clear Signal” on page 17-11.) Conditions associated with the subchannel and the chosen channel path, if any, affect (1) whether an attempt is made to issue the clear signal, and (2) whether the attempt to

issue the clear signal is successful. Independent of these conditions, the subchannel is subsequently set status pending, and the performance of the clear function is complete. These conditions and their effect on the clear function are described as follows:

### **No Attempt Is Made to Issue the Clear Signal:**

The channel subsystem does not attempt to issue the clear signal to the device if any of the following conditions exist:

1. No channel path was chosen. (See “Clear-Function Path Management” on page 15-13.)
2. The chosen channel path is no longer available for selection.
3. A channel-path-terminal condition exists for the chosen channel path.
4. The chosen channel path is currently being used to actively communicate with a different device.
5. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.
6. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

If any of the conditions above exist, the subchannel remains clear pending and is set status pending, and the performance of the clear function is complete.

### **The Attempt to Issue the Clear Signal Is Not Successful:**

When the channel subsystem attempts to issue the clear signal to the device, the attempt may not be successful because of the following conditions:

1. The control unit or device signals a busy condition when the channel subsystem attempts to select the device to issue the clear signal.
2. A path-not-operational condition is recognized when the channel subsystem attempts to select the device to issue the clear signal.
3. An error condition is encountered when the channel subsystem attempts to issue the clear signal.

If any of the conditions above exists and the channel subsystem either determines that the attempt to issue the clear signal was not successful or cannot determine whether the attempt was successful, the subchannel remains clear pending and is set status pending, and the performance of the clear function is complete.

**The Attempt to Issue the Clear Signal Is Successful:** When the channel subsystem determines that the attempt to issue the clear signal was successful, the subchannel is no longer clear pending and is set status pending, and the performance of the clear function is complete. When the subchannel becomes status pending, the I/O operation, if any, with the associated device has been terminated.

**Programming Note:** Subsequent to the performance of the clear function, any nonzero status, except control unit end alone, that is presented to the channel subsystem by the device is passed to the program as unsolicited alert status. Unsolicited status consisting of control unit end alone or zero status is not presented to the program.

---

## Halt Function

Subsequent to the execution of HALT SUBCHANNEL, the channel subsystem performs the halt function. Performance of the halt function consists of (1) performing a path-management operation, (2) issuing the halt signal to the associated device, and (3) causing the subchannel to be made status pending, indicating the completion of the halt function.

## Halt-Function Path Management

A path-management operation is performed as part of the halt function to examine channel-path conditions for the associated subchannel and to attempt to choose a channel path on which the halt signal can be issued to the associated device.

Channel-path conditions are examined in the following order:

1. If the channel subsystem is actively communicating or attempting to establish active communication with the device to be signaled, the channel path that is in use is chosen.

2. If the channel subsystem is in the process of accepting a no-longer-busy indication (which will not cause an interruption condition to be recognized) from the device to be signaled, and the associated subchannel has no allegiance to any channel path, the channel path that is in use is chosen.
3. If the associated subchannel has a dedicated allegiance for a channel path, that channel path is chosen.
4. If the associated subchannel has a working allegiance for one or more channel paths, one of those channel paths is chosen.
5. If the associated subchannel has no allegiance for any channel path, if a last-used channel path is indicated, and if that channel path is available for selection, that channel path is chosen. If that channel path is not available for selection, either no channel path is chosen or a channel path is chosen from the set of channel paths, if any, that are available for selection (as though no last-used channel path were indicated).
6. If the associated subchannel has no allegiance for any channel path, if no last-used channel path is indicated, and if there exist one or more channel paths that are available for selection, one of those channel paths is chosen.

If none of the channel-path conditions listed above apply, no channel path is chosen.

For item 4, for item 5 under the specified conditions, and for item 6, the channel subsystem chooses a channel path from a set of channel paths. In these cases, the channel subsystem may attempt to choose a channel path for which the following conditions *do not* apply:

1. A channel-path-terminal condition exists for the channel path.
2. Another subchannel has an active allegiance for the channel path.
3. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.

- The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

## Halt-Function Signaling and Completion

Subsequent to the attempt to choose a channel path, the channel subsystem, if conditions allow, attempts to select the device to issue the halt signal. (See "Halt Signal" on page 17-11.)

Conditions associated with the subchannel and the chosen channel path, if any, affect (1) whether an attempt is made to issue the halt signal, (2) whether the attempt to issue the halt signal is successful, and (3) whether the subchannel is made status pending to complete the halt function. These conditions and their effect on the halt function are described as follows:

### **No Attempt Is Made to Issue the Halt Signal:**

The channel subsystem does not attempt to issue the halt signal to the device if any of the following conditions exist:

- No channel path was chosen. (See "Halt-Function Path Management" on page 15-15.)
- The chosen channel path is no longer available for selection.
- A channel-path-terminal condition exists for the chosen channel path.
- The associated subchannel is status pending with other than intermediate status alone.
- The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.
- The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

If the conditions described in items 3, 5, or 6 exist, the associated subchannel remains halt pending until

those conditions no longer exist. When the conditions no longer exist (for the channel-path-terminal condition, when the condition no longer exists as a result of executing RESET CHANNEL PATH), the channel subsystem attempts to issue the halt signal to the device.

If any of the remaining conditions above exist, the subchannel remains halt pending and is set status pending, and the halt function is complete.

***The Attempt to Issue the Halt Signal Is Not Successful:*** When the channel subsystem attempts to issue the halt signal to the device, the attempt may not be successful because of the following conditions:

- The control unit or device signals a busy condition when the channel subsystem attempts to select the device to issue the halt signal.
- A path-not-operational condition is recognized when the channel subsystem attempts to select the device to issue the halt signal.
- An error condition is encountered when the channel subsystem attempts to issue the halt signal.

If the control unit or device signals a busy condition (item 1), the subchannel remains halt pending until the internal indication of busy is reset. When this event occurs, the channel subsystem again attempts to issue the halt signal to the device.

If any of the remaining conditions above exists and the channel subsystem either determines that the attempt to issue the halt signal was not successful or cannot determine whether the attempt was successful, then the subchannel remains halt pending and is set status pending, and the halt function is complete.

***The Attempt to Issue the Halt Signal Is Successful:*** When the channel subsystem determines that the attempt to issue the halt signal was successful and ending status, if appropriate, has been received at the subchannel, the subchannel is no longer halt pending and is set status pending, and the halt function is complete. When the subchannel becomes status pending, the I/O operation, if any, with the associated device has been terminated. The conditions that affect the receipt of ending status at the subchannel, and the effect of the halt signal at the device are described in the following discussion.

When the subchannel is subchannel-and-device active or only device active during the performance of the halt function, the state continues until the subchannel is made status pending because (1) the device has provided ending status or (2) the channel subsystem has determined that ending status is unavailable. When the subchannel is idle, start pending, start pending and resume pending, suspended, or suspended and resume pending, or when the halt signal is issued during command chaining after the receipt of device end but before the next command is transferred to the device, no operation is in progress at the device, and therefore no status is generated by the device as a result of receiving the halt signal. When the subchannel is neither subchannel active, nor status pending with intermediate status, and no errors are detected during the attempt to issue the halt signal to the device, an interruption condition indicating status pending alone is generated after the halt signal is issued.

The effect of the halt signal at the device depends partially on the type of device and its state. The effect of the halt signal on a device that is not active or that is performing a mechanical operation in which data is not transferred across the channel path, such as rewinding tape or positioning a disk-access mechanism, depends upon the control-unit or device model. If the device is performing a type of operation that is unpredictable in duration or in which data is transferred across the channel path, the control unit interprets the signal as one to terminate the operation. Pending status conditions at the device are not reset. When the control unit recognizes the halt signal, it immediately ceases all communication with the channel subsystem until it has reached the normal ending point. The control unit then requests selection by the channel subsystem to present any generated status.

If the subchannel is involved in the data-transfer portion of an I/O operation, data transfer is terminated during the performance of the halt function, and the device is logically disconnected from the channel path. If the halt function is addressed to a subchannel performing a chain of I/O operations and the device has already provided channel end for the current I/O operation, the channel subsystem causes the device to be disconnected and command chaining or command retry to be suppressed. If the subchannel is performing a chain of I/O operations with the device and the halt signal is issued during command chaining at a point after the receipt of device end for the previous I/O operation but before the next command is transferred to the device, the subchan-

nel is made status pending with primary and secondary status immediately after the halt signal is issued. The device-status field of the SCSW contains zeros in this case. If the halt function is addressed to a subchannel that is start pending and the halt-pending condition is recognized before initiation of the start function, initiation of the start function is not attempted, and the subchannel becomes status pending after the device has been signaled.

When the subchannel is not performing an I/O operation with the associated device, the device is selected, and an attempt is made to issue the halt signal as the device responds. If the subchannel is in the device-active state, the subchannel does not become status pending until it receives the device-end status from the halted device. If the subchannel is neither subchannel-and-device active nor device active, the subchannel becomes status pending immediately after selecting the device and issuing the halt signal. The SCSW for the latter case has the status-pending bit set to one (see "Status-Pending (Bit 31)" on page 16-18).

The termination of an I/O operation by performing the halt function may result in two distinct interruption conditions.

The first interruption condition occurs when the device generates the channel-end condition. The channel subsystem handles this condition as it would any other interruption condition from the device, except that the command address in the associated SCSW designates the point at which the I/O operation is terminated by containing the address of the last-executed CCW, plus 8, and the subchannel-status bits may reflect unusual conditions that were detected. If the halt signal was issued before all data designated for the operation had been transferred, incorrect length is indicated, subject to the control of the SLI flag in the current CCW. The value in the count field of the associated SCSW is unpredictable.

The second interruption condition occurs if device-end status was not presented with the channel-end interruption condition. In this situation, the subchannel-key, command-address, and count fields of the associated SCSW are not meaningful.

When HALT SUBCHANNEL terminates an I/O operation, the method of termination differs from that used upon exhaustion of count or upon detection of programming errors to the extent that termination by

HALT SUBCHANNEL is not contingent on the receipt of a service request from the associated device.

#### Programming Notes:

1. When, after an operation is terminated by HALT SUBCHANNEL, the subchannel is status pending with primary, primary and secondary, or secondary status, the extent of data transferred as described by the count field is unpredictable.
2. When the path that is chosen by the path-management operation has a channel-path-terminal condition associated with it, the halt function remains pending until the condition no longer exists. Until the condition is cleared, the associated subchannel cannot be used to perform I/O operations, even if other channel paths become available for selection. CLEAR SUBCHANNEL can be executed to terminate the halt-pending condition and make the subchannel usable.

---

## Start Function and Resume Function

Subsequent to the execution of START SUBCHANNEL and RESUME SUBCHANNEL, the channel subsystem performs the start and resume functions, respectively, to initiate an I/O operation with the associated device. Performance of a start or resume function consists of: (1) performing a path-management operation, (2) performing an I/O operation or chain of I/O operations with the associated device, and (3) causing the subchannel to be made status pending, indicating the completion of the start function. (Completion of a start function is described in "I/O Interruptions" on page 16-1.) The start function initiates the execution of a channel program that is designated in the ORB, which in turn is designated as the operand of START SUBCHANNEL, in contrast to the resume function that initiates the execution of a suspended channel program, if any, beginning at the CCW that caused suspension; otherwise, the resume function is performed as if it were a start function (see "Resume-Pending (Bit 20)" on page 16-13).

## Start-Function and Resume-Function Path Management

A path-management operation is performed by the channel subsystem during the performance of either a start or a resume function to choose an available channel path that can be used for device selection to initiate an I/O operation with that device. The actions taken are as follows:

1. If the subchannel is currently start pending and device active, the start function remains pending at the subchannel until the secondary status for the previous start function has been accepted from the associated device and the subchannel is made start pending alone. When the status is accepted and does not describe an alert interruption condition, the subchannel is not made status pending, and the performance of the pending start function is subsequently initiated. If the status describes an alert interruption condition, the subchannel becomes status pending with secondary and alert status, the pending start function is not initiated, deferred condition code 1 is set, and the start-pending bit remains one. If the subchannel is currently start pending alone, the performance of the start function is initiated as described below.
2. If a dedicated allegiance exists at the subchannel for a channel path, the channel subsystem chooses that path for device selection. If a busy condition is encountered while attempting to select the device and a dedicated allegiance exists at the subchannel, the start function remains pending until the internal indication of busy is reset for that channel path. When the internal indication of busy is reset, the performance of the pending start function is initiated on that channel path.
3. If no channel path is available for selection and no dedicated allegiance exists in the subchannel for a channel path, a channel path is not chosen.
4. If all channel paths that are available for selection have been tried and one or more of them are being used to actively communicate with other devices, or, alternatively, if the channel subsystem has encountered either a control-unit-busy or a device-busy condition on one or more of those channel paths, or a combination of those conditions on one or more of those channel paths, the start function remains pending at the

- subchannel until a channel path, control unit, or device, as appropriate, becomes available.
5. If (1) the start function is to be initiated on a channel path with a device attached to a type-1 control unit and (2) no other device is attached to the same control unit whose subchannel has either a dedicated allegiance to the same channel path or a working allegiance to the same channel path where primary status has not been received for that subchannel, then that channel path is chosen if it is available for selection; otherwise, that channel path is not chosen. If, however, another channel path to the device is available for selection and no allegiances exist as described above, that channel path is chosen. If no other channel path is available for selection, the start or resume function, as appropriate, remains pending until a channel path becomes available.
  6. If the device is attached to a type-3 control unit, and if at least one other device is attached to the same control unit whose subchannel has a dedicated allegiance to the same channel path, another channel path that is available for selection may be chosen, or the start function remains pending until the dedicated allegiance for the other device is cleared.
  7. If a channel path has been chosen and a busy indication is received during device selection to initiate the execution of the first command of a pending channel program, the channel path over which the busy indication is received is not used again for that device or control unit (depending on the device-busy or control-unit-busy indication received) until the internal indication of busy is reset.
  8. If, during an attempt to select the device in order to initiate the execution of the first command specified for the start or implied for the resume function (as described in action 7 on page 15-19), the channel subsystem receives a busy indication, it performs one of the following actions:
    - a. If the device is specified to be operating in the multipath mode and the busy indication received is device busy, then the start or resume function remains pending until the internal indication of busy is reset. (See “Multipath Mode (D)” on page 15-4.)
    - b. If the device is specified to be operating in the multipath mode and the busy indication received is control unit busy, or if the device is specified to be operating in the single-path mode, the channel subsystem attempts selection of the device by choosing an alternate channel path that is available for selection and continues the path-management operation until either the start or the resume function is initiated or selection of the device has been attempted on all channel paths that are available for selection. If the start or resume function has not been initiated by the channel subsystem after all channel paths available for selection have been chosen, the start or resume function remains pending until the internal indication of busy is reset.
    - c. If the subchannel has a dedicated allegiance, then action 2 on page 15-18 applies.
  9. When, during the selection attempt to transfer the first command, the device appears not operational and the corresponding channel path is operational for the subchannel, a path-not-operational condition is recognized, and the state of the channel path changes at the subchannel from operational for the subchannel to not operational for the subchannel (see “Path-Not-Operational Mask (PNOM)” on page 15-4). The path-not-operational conditions at the subchannel, if any, are preserved until the subchannel next becomes clear pending, start pending, or resume pending (if the subchannel was suspended), at which time the path-not-operational conditions are cleared. If, however, the corresponding channel path is not operational for the subchannel, a path-not-operational condition is not recognized. When the device appears not operational during the selection attempt to transfer the first command on a channel path that is available for selection, one of the following actions occurs:
    - a. If a dedicated allegiance exists for that channel path, then it is the only channel path that is available for selection; therefore, further attempts to initiate the start or resume function are abandoned, and an interruption condition is recognized.
    - b. If no dedicated allegiance exists and there are alternate channel paths available for selection that have not been tried, one of those channel paths is chosen to attempt

- device selection and transfer the first command.
- c. If no dedicated allegiance exists, no alternate channel paths are available for selection that have not been tried, and the device has appeared operational on at least one of the channel paths that were tried, the start or resume function remains pending at the subchannel until a channel path, a control unit, or the device, as appropriate, becomes available.
  - d. If no dedicated allegiance exists, no alternate channel paths are available for selection that have not been tried, and the device has appeared not operational on all channel paths that were tried, further attempts to initiate the start or resume function are abandoned, and an interruption condition is recognized.
10. When the subchannel is active and an I/O operation is to be initiated with a device, all device selections occur according to the LPUM indication if the multipath mode is not specified at the subchannel. For example, if command chaining is specified, the channel subsystem transfers the first and all subsequent commands describing a chain of I/O operations over the same channel path.

end signal or, in the case of command chaining, the channel-end signal for the last CCW of the chain. (See “Primary Interruption Condition” on page 16-4.) The device is active until the secondary interruption condition is recognized at the subchannel. Normally, the secondary interruption condition is caused by the device-end signal or, in the case of command chaining, the device-end signal for the last CCW of the chain. (See “Secondary Interruption Condition” on page 16-4.)

#### **Programming Notes:**

In the single-path mode, all transfers of commands, data, and status for the I/O operation or chain of I/O operations occur on the channel path over which the first command was transferred to the device.

When the device has the dynamic-reconnection feature installed, an I/O operation or chain of I/O operations may be performed in the multipath mode. To operate in the multipath mode, MODIFY SUBCHANNEL must have been previously executed for the subchannel with bit 13 of word 1 of the SCHIB specified as one. (See “Multipath Mode (D)” on page 15-4.) In addition, the device must be set up for the multipath mode by the execution of certain model-dependent commands appropriate to that type of device. The general procedures for handling multipath-mode operations are as follows:

#### **1. Setup**

- a. A set-multipath-mode type of command must be successfully executed by the device on each channel path that is to be a member of the multipath group being set up; otherwise, the multipath mode of operation may give unpredictable results at the subchannel. If, for any reason, one or more physically available channel paths to the device are not included in the multipath group, these channel paths must not be available for selection while the subchannel is operating in the multipath mode. A channel path can be made not available for selection by having the corresponding LPM bit set to zero either in the SCHIB prior to the execution of MODIFY SUBCHANNEL or in the ORB prior to the execution of START SUBCHANNEL.
- b. When a set-multipath-mode type of command is transferred to a device, only a single channel path must be logically available in

---

## **Execution of I/O Operations**

After a channel path is chosen, the channel subsystem, if conditions allow, initiates the execution of an I/O operation with the associated device. Execution of additional I/O operations may follow the initiation and execution of the first I/O operation. The channel subsystem can execute seven commands: write, read, read backward, control, sense, sense ID, and transfer in channel. Each command, except transfer in channel, initiates a corresponding I/O operation. Except for periods when channel-program execution is suspended at the subchannel (see “Suspension of Channel-Program Execution” on page 15-39), the subchannel is active from the acceptance of the first command until the primary interruption condition is recognized at the subchannel. If the primary interruption condition is recognized before the acceptance of the first command, the subchannel does not become active. Normally, the primary interruption condition is caused by the channel-

order to avoid alternate channel-path selection for the execution of that start function; otherwise, device-busy conditions may be detected by the channel subsystem on more than one channel path, which may cause unpredictable results for subsequent multipath-mode operations. This type of setup procedure should be used whenever the membership of a multipath group is changed.

## 2. Leaving the Multipath Mode

To leave the multipath mode and continue processing in the single-path mode, either of the following two procedures may be used:

- a. A disband-multipath-mode type of command may be executed for any channel path of the multipath group. This command must be followed by either (1) the execution of MODIFY SUBCHANNEL with bit 13 of word 1 of the SCHIB specified as zero, or (2) the specification of only a single channel path as logically available in the LPM. A start function must not be performed at a subchannel operating in the multipath mode with multiple channel paths available for selection while the device is operating in single-path mode; otherwise, unpredictable results may occur at the subchannel for that function or subsequent start functions.
- b. A resign-multipath-mode type of command is executed on each channel path of the multipath group (the reverse of the setup described in item 1 on page 15-20). This command must be followed by either (1) the execution of MODIFY SUBCHANNEL with bit 13 of word 1 of the SCHIB specified as zero, or (2) the specification of only a single channel path as logically available in the LPM. No start function may be performed at a subchannel operating in the multipath mode with multiple channel paths available for selection while the device is operating in single-path mode; otherwise, unpredictable results may occur at the subchannel for that or subsequent start functions.

## Blocking of Data

Data recorded by an I/O device is divided into blocks. The length of a block depends on the device; for

example, a block can be a card, a line of printing, or the information recorded between two consecutive gaps on magnetic tape.

The maximum amount of information that can be transferred in one I/O operation is one block. An I/O operation is terminated when the associated main-storage area is exhausted or the end of the block is reached, whichever occurs first. For some operations, such as writing on a magnetic-tape unit or at an inquiry station, blocks are not defined, and the amount of information transferred is controlled only by the program.

## Operation-Request Block

The operation-request block (ORB) is the operand of START SUBCHANNEL. The ORB specifies the parameters to be used in controlling that particular start function. These parameters include the interruption parameter, the subchannel key, the address of the first CCW, operation-control bits, numbers controlling priority, and a specification of the logical availability of channel paths.

The contents of the ORB are placed at the designated subchannel during the execution of START SUBCHANNEL, prior to the setting of condition code 0. If the execution will result in a nonzero condition code, the contents of the ORB are not placed at the designated subchannel.

The two rightmost bits of the ORB address must be zeros, placing the ORB on a word boundary; otherwise, a specification exception is recognized.

The format of the ORB is as follows:

Word

Interruption Parameter																																				
Key	SC	M	Y	F	P	I	A	U	O	H	T	LPM	L	D	0	0	0	X																		
Channel-Program Address																																				
CSS Priority	Reserved		CU Priority		Reserved		Reserved		Reserved		Reserved		Reserved		Reserved		Reserved																			
Reserved																																				
Reserved																																				
Reserved																																				
Reserved																																				

The fields in the ORB are defined as follows:

**Interruption Parameter:** Bits 0-31 of word 0 are preserved unmodified in the subchannel until replaced by a subsequent START SUBCHANNEL or MODIFY SUBCHANNEL instruction. These bits are placed in word 1 of the interruption code when an I/O interruption occurs and when an interruption request is cleared by the execution of TEST PENDING INTERRUPTION.

**Subchannel Key:** Bits 0-3 of word 1 form the subchannel key for all fetching of CCWs, IDAWs, MIDAWS, and output data and for the storing of input data associated with the start function initiated by START SUBCHANNEL. This key is matched with a storage key during these storage references. For details, see the section “Key-Controlled Protection” on page 3-10.

**Suspend Control (S):** Bit 4 of word 1 controls the performance of the suspend function for the channel program designated in the ORB. The setting of the S bit applies to all CCWs of the channel program designated by the ORB (see “Commands and Flags” on page 15-41).

When bit 4 is one, suspend control is specified, and channel-program suspension occurs when a suspend flag set to one is detected in a CCW. When bit 4 is zero, suspend control is not specified, and the presence of a suspend flag set to one in any CCW of the channel program causes a program-check condition to be recognized.

**Streaming-Mode Control (C):** Bit 5 of word 1 controls streaming-mode enablement for subchannels configured to FICON-converted-I/O-interface channel paths during performance of the specified start function. When bit 5 is zero, the streaming mode is enabled at the subchannel. When bit 5 is one, the streaming mode is disabled at the subchannel. Bit 5 is meaningful only for subchannels configured to FICON-converted-I/O-interface channel paths and is ignored for subchannels configured to other channel-path types.

When the streaming mode is enabled, the channel path considers the first command of the designated channel program to be in progress at the associated device when the channel path receives the indication that the command has been accepted at the device. In addition, the channel path's acceptance of status, under certain conditions, is recognized by the channel path without receiving acknowledgement of status acceptance from the device.

When the streaming mode is not enabled, the channel path does not consider the first command of the designated channel program to be in progress at the associated device until the appropriate channel-path response, indicating that the device-command response or status has been accepted at the channel path, is sent to the device. In addition, when the device sends status to the channel path, the channel path's acceptance of that status is not recognized at the channel path until the channel path's confirmation of acceptance is received and acknowledged by the device.

**Modification Control (M):** Bit 6 of word 1 specifies whether modification control is required for the channel program. When bit 6 is zero, modification control is specified. When bit 6 is one, modification control is not specified.

When modification control is specified, the channel subsystem forces command synchronization with the addressed I/O device each time a command is executed and the previously executed command has the PCI and chain-command flags set to one and the chain-data and suspend flags set to zero. When this condition is recognized, the channel subsystem signals a synchronization request to the I/O device for the current command. The channel subsystem temporarily suspends command chaining and does not fetch (or refetch) the next command-chained CCW until after normal ending status is received for the synchronizing command.

When modification control is not specified, then command synchronization is not required, and the channel subsystem may transfer commands to the I/O device without waiting for status.

The M bit is meaningful only for subchannels configured to FICON-I/O-interface or FICON-converted-I/O-interface channel paths and is ignored for other subchannels configured to other channel-path types.

#### Programming Notes:

1. For FICON-I/O-interface and FICON-converted-I/O-interface channel paths, modification control provides the capability to optimize dynamically modified channel programs that use the PCI flag in the CCW to initiate channel-program modification. Specifically, it allows the program to delay the channel-subsystem fetching and transferring of commands until after status is received for the command following the command with the PCI

bit set. This increases the likelihood that a program-controlled interruption will be accepted by a CPU and acted upon by the program that dynamically modifies one or more command-chained CCWs that follow the synchronizing command.

In order to increase the probability that any dynamically modified CCWs are fetched after their modification and not prior to their modification, the modifying program should be executed as soon as possible following the CPU's acceptance of the program-controlled interruption. Additionally, the program should minimize the periods during which the configured CPUs are disabled for I/O interruptions.

For channel paths other than FICON-I/O-interface or FICON-converted-I/O-interface channel paths, command synchronization is implicit in the signalling protocol between the channel subsystem and the I/O device; therefore no explicit programming action is required to force command synchronization. Regardless, the program should still attempt to accept and process program-controlled interruptions for these channel-path types in as timely a manner as possible for the same reason as stated above.

2. In order to allow the channel subsystem to optimize the execution of channel programs for FICON-I/O-interface or FICON-converted-I/O-interface channel paths, use of the modification-control facility is discouraged except for channel programs that require dynamic modification.

**Synchronization Control (Y):** Bit 7 of word 1 specifies whether synchronization control is required for the channel program. When bit 7 is zero and the prefetch-control bit, bit 9 of word 1, is one, synchronization control is specified. When bit 7 is one and bit 9 is one, synchronization control is not specified.

When synchronization control is specified, the channel subsystem forces command synchronization with the addressed I/O device whenever the current command in execution describes an input operation and the next CCW to be fetched describes an output operation. When this condition is recognized, the channel subsystem signals a synchronization request to the I/O device when the input command is transferred. The transfer of the output command is held pending at the subchannel until normal ending status, signaling the completion of the performance of the input operation by the I/O device, is received. Upon receipt of the ending status, the channel sub-

system fetches (or refetches) the data associated with the output command and transfers it to the I/O device.

When synchronization control is not specified, the channel subsystem may transfer commands of the channel program without awaiting status that would signal the completion of the I/O operation for each command.

The Y bit is meaningful only when the subchannel is configured to FICON-I/O-interface or FICON-converted-I/O-interface channel paths and the prefetch-control bit, bit 9 of word 1, is one. The Y bit is ignored for subchannels configured to other channel-path types and when the prefetch-control bit is zero. **Format Control (F):** Bit 8 of word 1 specifies the format of the channel-command words (CCWs) that make up the channel program designated by the channel-program-address field. When bit 8 of word 1 is zero, format-0 CCWs are specified. When bit 8 is one, format-1 CCWs are specified. (See "Channel-Command Word" on page 15-26 for the definition of the CCW formats.)

**Prefetch Control (P):** Bit 9 of word 1 specifies whether or not unlimited prefetching of CCWs is allowed for the channel program. When bit 9 is one, unlimited prefetching of CCWs is allowed. (Unlimited prefetching of data, IDAWs, and MIDAWs, associated with the current and prefetched CCWs is always allowed.) It is model dependent whether prefetching is actually performed.

When bit 9 of word 0 is zero, no prefetching is allowed, except in the case of data chaining on output, where the prefetching of one CCW describing a data area is allowed. When bit 9 of word 0 is zero, the synchronization-control bit, bit 7 of word 1, is ignored.

Additional controls may limit the scope of prefetching.

**Initial-Status-Interrupt Control (I):** Bit 10 of word 1 specifies whether or not the channel subsystem must verify to the program that the device has accepted the first command associated with a start or resume function. When the I bit is specified as one in the ORB, then, when the subchannel becomes active, indicating that the first command has been accepted for this start or resume function, the Z bit (see "Zero Condition Code (Z)" on page 16-11) is set to one at this subchannel, and the subchannel becomes status pending with intermediate status.

If the subchannel does not become active — for example, when the device signals channel end immediately upon receiving the first command, command chaining is not specified in the CCW, and command retry is not signaled — the command-accepted condition (Z bit set to one) is not generated; instead, the subchannel becomes status pending with primary status. Intermediate status may also be indicated in this case when the command is accepted if the first CCW contained the PCI flag set to one.

**Address-Limit-Checking Control (A):** When the address-limit-checking facility is installed, bit 11 of word 1 specifies whether or not address-limit checking is specified for the channel program. When this bit is zero, no address-limit checking is performed for the execution of the channel program, independent of the setting of the limit-mode bits in the subchannel (see “Limit Mode (LM)” on page 15-2). When this bit is one, address-limit checking is allowed for the channel program, subject to the setting of the limit-mode bits in the subchannel.

When the address-limit-checking facility is not installed, the address-limit-checking-control bit (A) must be zero in the ORB when START SUBCHANNEL is executed; otherwise, an operand exception is recognized.

**SUPPRESS-SUSPENDED-INTERRUPTION Control (U):** Bit 12 of word 1, when one, specifies that the channel subsystem is to suppress the generation of an intermediate interruption condition due to suspension if the subchannel becomes suspended. When bit 12 is zero, the channel subsystem generates an intermediate interruption condition whenever the subchannel becomes suspended during the execution of the channel program.

#### **Format-2-IDAW Control (H):**

Bit 14 of word 1 specifies the format of IDAWs for CCWs that specify indirect data addressing. When bit 14 of word 1 is one, format-2 (64-bit data address) IDAWs are provided for all CCWs that have the IDAW flag set to one in the CCW. When bit 14 of word 1 is zero, format-1 (31-bit data address) IDAWs are provided for all CCWs that have the IDAW flag set to one in the CCW.

**Programming Note:** Format-2 IDAWs and MIDAWs provide the only means by which data can be transferred directly between an I/O device and storage locations with addresses greater than 2G bytes.

**2K-IDAW Control (T):** Bit 15 of word 1 specifies the main-storage block size for format-2-IDAW data areas. Bit 15 is meaningful only when bit 14 (format-2 IDAW control) is one and is ignored when bit 14 is zero. When bit 15 of word 1 is one, all format-2 IDAWs designate 2K-byte storage blocks. When bit 15 of word 1 is zero, all format-2 IDAWs designate 4K-byte storage blocks.

Bit 13 of word 1 is reserved for future use and must be zero; otherwise, either an operand exception or a program-check condition is recognized.

**Logical-Path Mask (LPM):** Bits 16-23 of word 1 are preserved unmodified in the subchannel and specify to the channel subsystem which of the logical paths 0-7 are to be considered logically available, as viewed by the program. A bit setting of one means that the corresponding channel path is logically available; a zero specifies that the corresponding channel path is logically not available. If a channel path is specified by the program as being logically not available, the channel subsystem does not use that channel path to perform clear, halt, resume, or start functions when requested by the program, except when a dedicated-allegiance condition exists for that channel path. If a dedicated-allegiance condition exists, the setting of the LPM is ignored, and a resume, start, halt, or clear function is performed by using the channel path having the dedicated allegiance.

**Incorrect-Length-Suppression Mode (L):** When bit 8 of word 1 is one, then bit 24 of word 1, when one, specifies the incorrect-length-suppression mode. When the subchannel is in this mode when an immediate operation occurs (that is, when a device signals the channel-end condition during initiation of the command) and the current CCW contains a non-zero value in bit positions 16-31, indication of an incorrect-length condition is suppressed.

When bit 8 of word 1 is one, then bit 24 of word 1, when zero, specifies the incorrect-length-indication mode. When the subchannel is in this mode when an immediate operation occurs (that is, when a device signals the channel-end condition during initiation of the command) and the current CCW contains a non-zero value in bit positions 16-31, indication of an incorrect-length condition is recognized. Command chaining is suppressed unless the SLI flag in the CCW is one and the chain-data flag is zero.

When bit 8 of word 1 is zero, the value of bit 24 is ignored by the channel subsystem, and the subchannel is in the incorrect-length-suppression mode.

**Modified-CCW-Indirect-Data-Addressing Control (D):** When the modified-CCW-indirect-data-addressing facility is installed, bit 25 of word 1 specifies whether the channel program may include CCWs that specify modified-CCW-indirect-data-address lists. When bit 25 of word 1 is one, the channel program may include CCWs that specify lists of quadwords each called a modified-CCW-indirect-data-address word (MIDAW). When bit 25 of word 1 is zero, the channel program may not include CCWs that specify modified-CCW-indirect-data-address lists.

When the modified-CCW-indirect-data-addressing facility is not installed, the modified-CCW-indirect-data-addressing control must be zero in the ORB when START SUBCHANNEL is executed; otherwise, an operand exception is recognized.

**ORB-Extension Control (X):** Bit 31 of word 1 specifies whether the ORB is extended. When bit 31 of word 1 is zero, the ORB consists of words 0-2, and words 3-7 are ignored. When bit 31 of word 1 is one, the ORB consists of words 0-7. Words 0 and 1 are described above. Words 2-7 are described below.

**Reserved:** Bits 26-30 of word 1 are reserved for future use and must be set to zeros. Bit 31 of word 1 must be zero if the ORB-extension facility is not installed. Otherwise, an operand exception or program-check condition is recognized.

**Channel-Program Address:** Bits 1-31 of word 2 specify the absolute address of the first CCW in main storage. Bit 0 of word 2 must be zero; otherwise, either an operand exception or a program-check condition is recognized. If format-0 CCWs are specified by bit 8 of word 1, then bits 1-7 of word 2 also must be zeros; otherwise, a program-check condition is recognized.

The three rightmost bits of the channel-program address must be zeros, designating the CCW on a doubleword boundary; otherwise, a program-check condition is recognized.

If the channel-program address designates a location protected against fetching or designates a location outside the storage of the particular installation, the start function is not initiated at the device. In this situ-

ation, the subchannel becomes status pending with primary, secondary, and alert status.

**Channel-Subsystem (CSS) Priority:** When bit 31 (X) of word 1 of the ORB is one, byte 0 of word 3 contains an unsigned binary integer, called the channel-subsystem-priority number, that is assigned to the designated subchannel and used to order the selection of subchannels when either a start function or a resume function is to be initiated for one or more subchannels that are start pending or resume pending.

The specified channel-subsystem-priority number can be any number in the range of 0 to 255. The numbers 0 and 255 designate the lowest and highest priorities, respectively.

Depending on the model and the configuration:

1. Fewer than 256 priority levels may be provided. For such models, the ORB-specified priority number may be ignored, and an alternative priority number may be implicitly assigned to the subchannel when the subchannel becomes start pending.
2. When bit 31 (X) of word 1 of the ORB is zero, an implicit priority number is assigned to the subchannel.

See “Channel-Subsystem-I/O-Priority Facility” on page 17-28 for details about how the priority number is assigned for both of these cases.

**Control-Unit (CU) Priority:** When bit 31 (X) of word 1 of the ORB is one, byte 2 of word 3 contains an unsigned binary integer, called the control-unit-priority number, that specifies, for an associated control unit attached by a FICON channel path, the priority level that is applied at the associated control unit for all I/O operations associated with the start function.

The specified control-unit-priority number can be any integer in the range of 1 to 255. The numbers 1 and 255 designate the lowest and highest priorities, respectively. The number 0 designates that no priority is assigned to the I/O operations associated with the start function. The handling of I/O operations when the priority number is 0 depends on the control-unit model.

Also depending on the control-unit model, fewer than 255 priority levels may be supported by the control

unit. See the control-unit's System Library publication for additional information regarding the range of priority numbers supported and how this priority number is used.

The specified control-unit-priority number is ignored if any of the following conditions exists:

1. Bit 31 (X) of word 1 is zero. In this case, a control-unit-priority number of 0 is transmitted in the associated outbound frames.
2. The designated subchannel is not associated with a control unit configured to a FICON channel path.
3. The associated control unit does not provide prioritized performance of I/O operations. In this case, the control-unit-priority number in the associated outbound frames is ignored at the control unit.
4. The channel-subsystem model does not provide for the transmission of the control-unit-priority number.
5. The channel-subsystem-I/O-priority facility is not operational due to an operator action.

**Reserved:** All fields in the ORB that are defined as either "0" or "Reserved" must contain zeros when START SUBCHANNEL is executed; otherwise, either an operand exception or a program-check condition is recognized.

#### Programming Notes:

1. Bit positions of the ORB that presently are specified to contain zeros may in the future be assigned for the control of new functions.
2. The interruption parameter may contain any information, but ordinarily the information is of significance to the program handling the I/O interruption.

## Channel-Command Word

The channel-command word (CCW) specifies the command to be executed and, for commands initiating certain I/O operations, it designates the storage area associated with the operation, the action to be taken whenever transfer to or from the area is completed, and other options.

A channel program consists of one or more CCWs that are logically linked such that they are fetched and executed by the channel subsystem in either a sequential or a nonsequential order. Sequential (contiguous) CCWs are linked by the use of the chain-data and chain-command flags, and nonsequential (noncontiguous) CCWs are linked by a CCW specifying the transfer-in-channel command.

As each CCW is executed, it is recognized as the current CCW. A CCW becomes current (1) when it is the first CCW of a channel program and has been fetched, (2) when, during command chaining, the new CCW is logically fetched, or (3) when, during data chaining, the new CCW takes over control of the I/O operation (see "Data Chaining" on page 15-31). When chaining is not specified, a CCW is no longer current after TEST SUBCHANNEL clears the start-function bit in the subchannel.

The location of the first CCW of the channel program is designated in the ORB that is the operand of START SUBCHANNEL. The first CCW is fetched subsequent to the execution of the instruction. The format of the CCWs fetched by the channel subsystem is specified by bit 8 of word 1 of the ORB. Each additional CCW in the channel program is obtained when the CCW is needed. Fetching of the CCWs by the channel subsystem does not affect those locations in main storage.

CCWs have either of two different formats, format 0 or format 1. The two formats do not differ in the information contained in the CCW, but they do differ in the size of the address and the arrangement of fields within the CCW.

The formats are defined as follows:

### Format-0 CCW

Cmd Code	Data Address		
0	8		31
Flags	/ / / / / /	Count	63

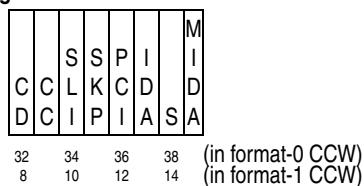

32            40            48            63

### Format-1 CCW

0	Cmd Code	Flags	Count	
0	8	16	31	
1	Data Address			

32            63

### Flags

Format-0 CCWs can be located anywhere in the first  $2^{24}$  (16M) bytes of absolute storage, and format-1 CCWs can be located anywhere in the first  $2^{31}$  (2G) bytes of absolute storage.

If indirect data addressing is specified and the format-2-IDAW-control bit is zero in the ORB associated with the CCW, then:

1. Bits 30 and 31 (format 0) or 62 and 63 (format 1) of the CCW must be zeros, designating a word boundary,
2. Bit 0 of the first entry of the indirect-data-address list must be zero.
3. The MIDA flag must be zero.

If indirect data addressing is specified and the format-2-IDAW-control bit is one in the ORB associated with the CCW, bits 29-31 (format 0) or bits 61-63 (format 1) of the CCW must be zeros, designating a doubleword boundary.

If modified indirect data addressing is specified, then:

1. The modified-CCW-indirect-data-addressing-control bit in the ORB must be one.

2. Bits 28-31 (format 0) or bits 60-63 (format 1) of the CCW must be zeros, designating a quadword boundary.
3. The CCW SKP and IDA flags must be zero.
4. The MIDAW count field must be greater than zero.
5. The combination of the MIDAW count and data-address fields must not specify the transfer of data across a 4K-byte boundary, unless skipping is in effect for the MIDAW.
6. Reserved bits in the first entry of the modified-CCW-indirect-data-address list must be zero.

When any of these requirements is not met, a program-check condition may be recognized (see “CCW Indirect Data Addressing” on page 15-35 and “Modified CCW Indirect Data Addressing” on page 15-37). Detection of this condition during data chaining causes the I/O device to be signaled to conclude the operation. When a failure to meet these requirements is detected during command chaining or subsequent to the execution of START SUBCHANNEL, the new operation is not initiated, and an interruption condition is generated.

The contents of bit positions 40-47 of a format-0 CCW are ignored.

The fields in the CCWs are defined as follows:

**Command Code:** Bits 0-7 (both formats) specify the operation to be performed.

**Data Address:** Bits 8-31 (format 0) or bits 33-63 (format 1) designate a location in absolute storage. The designated location is the first location referred to in the area designated by the CCW. Bit 32 of a format-1 CCW must be zero; otherwise, a program-check condition is recognized. If a byte count of zero is specified, this field is not checked.

When the MIDA flag is one, the data-address field must designate an absolute storage location that is on a quadword boundary; otherwise, a program-check condition is recognized.

See “CCW Indirect Data Addressing” on page 15-35 and “Modified CCW Indirect Data Addressing” on page 15-37 for information about the specification of data addresses greater than 2G bytes.

**Chain-Data (CD) Flag:** Bit 32 (format 0) or bit 8 (format 1), when one, specifies chaining of data. The bit causes the storage area designated by the next CCW to be used with the current I/O operation. When the CD flag is one in a CCW, the chain-command and suppress-length-indication flags (see below) are ignored.

**Chain-Command (CC) Flag:** Bit 33 (format 0) or bit 9 (format 1), when one, and when the CD flag and S flag are both zeros, specifies chaining of commands. The bit causes the operation specified by the command code in the next CCW to be initiated upon the normal completion of the current operation.

**Suppress-Length-Indication (SLI) Flag:** Bit 34 (format 0) or bit 10 (format 1) controls whether an incorrect-length condition is to be indicated to the program. When this bit is one and the CD flag is zero, the incorrect-length indication is suppressed. When both the CC and SLI flags are ones and the CD flag is zero, command chaining takes place, regardless of the presence of an incorrect-length condition. This bit should be specified in *all* CCWs where suppression of the incorrect-length indication is desired.

**Skip (SKP) Flag:** Bit 35 (format 0) or bit 11 (format 1), when one, specifies the suppression of transfer of information to storage during a read, read-backward, sense ID, or sense operation. This bit must be zero when the MIDA flag is one; otherwise, a program-check condition is recognized.

**Program-Controlled-Interruption (PCI) Flag:** Bit 36 (format 0) or bit 12 (format 1), when one, causes the channel subsystem to generate an intermediate interruption condition when the CCW containing the bit takes control of the I/O operation. When the PCI flag bit is zero, normal operation takes place.

**Indirect-Data-Address (IDA) Flag:** Bit 37 (format 0) or bit 13 (format 1), when one, specifies indirect data addressing. This bit must be zero when the MIDA flag is one; otherwise, a program-check condition is recognized.

**Suspend (S) Flag:** Bit 38 (format 0) or bit 14 (format 1), when one, specifies suspension of channel-program execution. When valid, it causes channel-program execution to be suspended prior to the execution of the CCW containing the S flag. A one value of the S flag is valid when bit 4 of word 1 of the associated ORB is one.

**Modified-Indirect-Data-Address (MIDA) Flag:** Bit 39 (format 0) or bit 15 (format 1), when one, specifies modified indirect data addressing. This bit must be zero when the modified-CCW-indirect-data-addressing-control bit in the ORB is zero, the CCW IDA flag is one, the CCW SKP flag is one, or the channel paths associated with the subchannel do not support modified CCW indirect data addressing; otherwise, a program-check condition is recognized.

**Count:** Bits 48-63 (format 0) or bits 16-31 (format 1) specify the number of bytes in the storage area designated by the CCW.

## Command Code

The command code, bit positions 0-7 of the CCW, specifies to the channel subsystem and the I/O device the operation to be performed.

The two rightmost bits or, when these bits are zeros, the four rightmost bits of the command code identify the operation to the channel subsystem. The channel subsystem distinguishes among the following four operations:

- Output forward (write, control)
- Input forward (read, sense, sense ID)
- Input backward (read backward)
- Branching (transfer in channel)

The channel subsystem ignores the leftmost four bits of the command code in a format-0 CCW that specifies transfer-in-channel. In a format-1 CCW that specifies transfer in channel, all bits of the command code are decoded by the channel subsystem.

Commands that initiate I/O operations (write, read, read backward, control, sense, and sense ID) cause all eight bits of the command code to be transferred to the control unit. In these command codes, the left-most bit positions contain modifier bits. The modifier bits specify to the device how the command is to be executed. They may, for example, cause the device to compare data received during a write operation with data previously recorded, and they may specify such attributes as recording density and parity. For the control command, the modifier bits may contain the order code specifying the control function to be performed. The meaning of the modifier bits depends on the type of I/O device and is specified in the System Library publication for the device.

The command-code assignment is listed in Figure 15-5 on page 15-29. The symbol x indicates that the bit position is ignored; the symbol m identifies a modifier bit.

Code	Command	
x x x x	0 0 0 0	Invalid
m m m m	m m 0 1	Write
m m m m	m m 1 0	Read
m m m m	1 1 0 0	Read Backward
m m m m	m m 1 1	Control
m m m m	0 1 0 0	Sense
1 1 1 0	0 1 0 0	Sense ID
x x x x	1 0 0 0	Transfer in channel <sup>1</sup>
0 0 0 0	1 0 0 0	Transfer in channel <sup>2</sup>
m m m m	1 0 0 0	Invalid <sup>3</sup>

**Explanation:**

m Modifier bit  
 x Ignored  
 1 Format-0 CCW  
 2 Format-1 CCW  
 3 Format-1 CCW with any of bits 0-3 nonzero

Figure 15-5. Command-Code Assignment

Whenever the channel subsystem detects an invalid command code during the initiation of command execution, the program-check-interruption condition is generated, and channel-program execution is terminated. The command code is ignored during data chaining, unless it specifies transfer in channel.

## Designation of Storage Area

The main-storage area associated with an I/O operation is defined by one or more CCWs. A CCW defines an area by specifying the address of the first byte to be transferred and the number of consecutive bytes contained in the area. The address of the first byte of data to be transferred is specified either directly in the data-address field of the CCW or indirectly in an indirect-data-address word (IDAW) or modified-indirect-data-address word (MIDAW) designated by the data-address field of the CCW. The number of bytes contained in the storage area is specified in the count field.

In write, read, control, and sense operations, storage locations are used in ascending order of addresses. As information is transferred to or from main storage, the address from the address field is incremented, and the count from the count field is decremented.

The read-backward operation places data in storage in a descending order of addresses, and both the count and the address are decremented. When the count reaches zero, the storage area defined by the CCW is exhausted.

Any main-storage location available to the start function can be used in the transfer of data to or from an I/O device, provided that the location is not protected against that type of reference. Format-0 CCWs can be located in any available part of the first  $2^{24}$  (16M) bytes of absolute storage, and format-1 CCWs can be located in any available part of the first  $2^{31}$  (2G) bytes of absolute storage, provided that, in both cases, the location is not protected against a fetch-type reference. When the channel subsystem attempts to refer to a protected location, the protection-check condition is generated, and the device is signaled to terminate the operation.

A main-storage location is available if it is available in the configuration and access to the location is not prevented by the address-limit-checking facility. CCWs, IDAWs, MIDAWs, and the data they address reside in main-storage locations. If a main-storage location is not available, it is said to have an invalid address.

If the channel subsystem refers to a location that is not available, the program-check condition is generated. When the first CCW designated by the channel-program address is at an unavailable location, the start function is not initiated at the device, the status portion of the SCSW is updated with the program-check indication, the subchannel becomes status pending with primary, secondary, and alert status, and deferred condition code 1 is indicated. An invalid data address, as well as any invalid CCW address detected on chaining or subsequent to the execution of START SUBCHANNEL, causes the channel subsystem to signal the device to conclude the operation, if and when the device requests or offers a byte of data or status at the invalid address. In this situation, the subchannel is made status pending with program check indicated in the subchannel status, and the device status is a function of the status received from the device. The program-check condition causes command chaining and command retry to be suppressed.

During an output operation, the channel subsystem may fetch data from main storage before the time the I/O device requests the data. Any number of bytes specified by the current CCW may be prefetched and

buffered. When data chaining during an output operation, the channel subsystem may fetch one CCW describing a data area at any time during the execution of the current CCW. If unlimited prefetching is allowed by the setting of the prefetch-control bit in the ORB, any number of CCWs, IDAWs, and MIDAWs and the associated data may be prefetched by the channel subsystem. When the I/O operation uses data and CCWs from locations near the end of the available storage, such prefetching may cause the channel subsystem to refer to locations that do not exist. Invalid addresses detected during prefetching do not affect the performance of the I/O operation and do not cause error indications until the operation actually attempts to use the information. If the operation is concluded by the I/O device or by the execution of HALT SUBCHANNEL or CLEAR SUBCHANNEL before the invalid information is needed, the condition is not brought to the attention of the program.

The count field in the CCW can specify any number of bytes up to 65,535. In format-0 CCWs, the count field is always nonzero unless the command code specifies transfer in channel, in which case the count field is ignored. In format-1 CCWs, the count field may contain the value zero unless data chaining is specified or the CCW is fetched while data chaining. Whenever (1) the count field in a format-1 CCW is zero, (2) data chaining is either not specified or not in effect, and (3) data transfer is requested by the device, the device is signaled to stop, and the I/O operation is terminated. The channel subsystem sets the incorrect-length condition if the SLI flag is not one in the CCW. No data is transferred. If the device does not request data transfer, the operation proceeds to the normal ending point.

If a zero byte count is contained in a format-0 CCW that does not specify transfer in channel, or if a zero byte count is contained in a format-1 CCW that specifies data chaining or was fetched while data chaining, a program-check condition is recognized, and the subchannel is made status pending with combinations of primary, secondary, and alert status as a function of the state of the subchannel and the status received from the device.

**Note:** For a description of the storage area associated with a CCW when indirect data addressing is used, see "CCW Indirect Data Addressing" on page 15-35.

### Programming Notes:

1. Since a format-1 CCW with a count of zero is valid, the program can use the CCW count field to specify that no data be transferred to the I/O device. If the device requests a data transfer, the device is signaled to terminate data transfer. If the SLI and chain-command flags are also specified as ones, and no unusual conditions are encountered subsequent to signaling the device to terminate data transfer, the new operation is initiated upon receipt of device end from the device.
2. If the subchannel is in the incorrect-length-suppression mode, the chain-data flag in the current CCW is zero, and the operation is performed as an immediate operation, then incorrect length is not indicated, regardless of the setting of the SLI flag.

If the subchannel is in the incorrect-length-indication mode, if the chain-data flag in the current CCW is zero, and if the operation is performed as an immediate operation, then incorrect length is indicated if the count field of the current CCW specifies a nonzero value, unless suppressed by the SLI flag of the CCW; incorrect length is not indicated, however, if the count field of the CCW specifies a value of zero.

If a new CCW that has a count field of zero is fetched during data chaining or if a CCW is fetched with the chain-data flag set to one and a count field of zero, a program-check condition is recognized by the channel subsystem.

### Chaining

When the channel subsystem has completed the transfer of information specified by a CCW, it can continue performing the start function by fetching a new CCW. Such fetching of a new CCW is called chaining, and the CCWs belonging to such a sequence are said to be chained.

Chaining takes place between CCWs located in successive doubleword locations in storage. It proceeds in an ascending order of addresses; that is, the address of the new CCW is obtained by adding 8 to the address of the current CCW. Two chains of CCWs located in noncontiguous storage areas can be coupled for chaining purposes by a transfer-in-channel command. All CCWs in a chain apply to the

I/O device that is associated with the subchannel designated by the original START SUBCHANNEL instruction.

Two types of chaining are provided: chaining of data and chaining of commands. Chaining is controlled by the chain-data (CD) and chain-command (CC) flags in conjunction with the suppress-length-indication (SLI) flag in the CCW. These flags specify the action to be taken by the channel subsystem upon the exhaustion of the current CCW and upon receipt of ending status from the device, as shown in Figure 15-6 on page 15-31.

The specification of chaining is effectively propagated through a transfer-in-channel command. When, in the process of chaining, a transfer-in-channel command is fetched, the CCW designated by the transfer-in-channel command is used for the type of chaining specified in the CCW preceding the transfer-in-channel command.

The CD and CC flags are ignored in a format-0 CCW specifying the transfer-in-channel command. In a format-1 CCW specifying the transfer-in-channel command, the CD and CC flags must be zeros; otherwise, a program-check condition is recognized.

Flags in Current CCW			Action at the Subchannel upon Exhaustion of Count or Receipt of Channel End						
			Immediate Operation				Non-immediate Operation		
			Incorrect-Length-Suppression Mode <sup>1</sup>		Incorrect-Length-Indication Mode		Count Exhausted		Count Not Exhausted and CE Received
CD	CC	SLI	CCW Count≠0	CCW Count=0	CCW Count≠0	CCW Count=0	Ce Not Received	Ce Received	
0	0	0	End, NIL	End, NIL	End, IL	End, NIL	Stop, IL	End, NIL	End, IL
0	0	1	End, NIL	End, NIL	End, NIL	End, NIL	Stop, NIL	End NIL,	End, NIL
0	1	0	CC	CC	CC	CC	CC	CC	End, IL
0	1	1	CC	CC	CC	CC	Stop, CC	CC	CC
1	-	-	End, NIL	PC	End, IL	PC	CD	*	End IL

**Explanation:**

- The selected bit is ignored and may be either zero or one.
- \* These situations cannot validly occur. When data chaining is specified, the new CCW takes control of the operation after transferring the last byte of data designated by the current CCW, but before the next request for data or status transfer from the device. The new CCW (which cannot contain a count of zero unless a program-check condition is also recognized) is in control of the operation.
- <sup>1</sup> The count field must contain a nonzero value when format-0 CCWs are specified; otherwise, the operation is terminated with a program-check condition.

CC Command chaining is performed by the channel subsystem upon receipt of device end.

CD The chain-data flag causes the channel subsystem to immediately fetch a new CCW for the same operation. The operation continues unless the CCW thus fetched has a count field of zero, in which case the operation is terminated with a program-check condition.

CE Channel end from the device that indicates end of block.

End Operation is terminated.

IL Incorrect length is indicated with the subsequent interruption condition generated at the subchannel.

NIL Incorrect length is not indicated with the subsequent interruption condition generated at the subchannel.

PC These situations cannot validly occur. The channel subsystem recognizes a program-check condition when a CCW is fetched that has the chain-data flag set to one and a count field of zero.

STOP Device is signaled to terminate data transfer, but subchannel remains subchannel active until channel end is received.

Figure 15-6. Subchannel Chaining Action

**Programming Note:** When bit 9 of word 1 of the ORB is one, unlimited prefetching of chained CCWs (including CCWs linked by a transfer-in-channel command) by the channel subsystem is permitted. When prefetching is allowed by the ORB, no modification of the channel program should be performed after START SUBCHANNEL is executed and before the

primary interruption condition for the operation has been received unless the subchannel is currently suspended and is not resume pending.

## Data Chaining

During data chaining, the new CCW fetched by the channel subsystem defines a new storage area for

the original I/O operation. If the channel path is of the parallel-I/O-interface type, the performance of the operation at the I/O device is not affected. If the channel path is of the serial-I/O-interface type, then the performance of the operation at the I/O device either is not affected or, depending on the device model, may be terminated with unit-check status. When the operation at the I/O device is not affected and all data designated by the current CCW has been transferred to main storage or to the device, data chaining causes the operation to continue, using the storage area designated by the new CCW. The contents of the command-code field of the new CCW are ignored, unless they specify transfer in channel.

Data chaining is considered to occur immediately after the last byte of data designated by the current CCW has been transferred to main storage or to the device. When the last byte of the data transfer has been placed in main storage or accepted by the device, the new CCW takes over the control of the operation. If the device sends channel end after exhausting the count of the current CCW but before transferring any data to or from the storage area designated by the new CCW, the SCSW associated with the concluded operation pertains to the new CCW.

If programming errors are detected in the new CCW or during its fetching, the error indication is generated, and the device is signaled to conclude the operation when it attempts to transfer data designated by the new CCW. If the device signals the channel-end condition before transferring any data designated by the new CCW, program check or protection check is indicated in the SCSW associated with the termination. The contents of the SCSW pertain to the new CCW unless the address of the new CCW is invalid, the location is protected against fetching, or programming errors are detected in an intervening transfer-in-channel command. A data address referring to a nonexistent or protected area causes an error indication only after the I/O device has attempted to transfer data to or from the invalid location.

Data chaining during an input operation causes the new CCW to be fetched when all data designated by the current CCW has been placed in main storage. On an output operation, the channel subsystem may fetch the new CCW from main storage before data chaining occurs. Any programming errors in the prefetched CCW, however, do not affect the performance of the operation until all data designated by the current CCW has been transferred to the I/O device. If the device concludes the operation before

all data designated by the current CCW has been transferred, the conditions associated with the prefetched CCW are not indicated to the program. Unlimited prefetching is allowed under the control of the prefetch bit specified in the ORB. (See “Prefetch Control (P)” on page 15-23.) When unlimited prefetching is not allowed and an output operation is specified, only one CCW describing a data area may be prefetched. If a prefetched CCW specifies transfer in channel, only one more CCW may be fetched before the exhaustion of the current CCW.

#### Programming Notes:

1. If the ORB does not specify unlimited prefetching, no prefetching of CCWs is performed, except in the case of data chaining on an output operation where one CCW describing a data area may be prefetched at a time.

If the ORB for the I/O operation specifies that prefetching is allowed, any number of CCWs, IDAWs, and MIDAWs and the associated data areas may be prefetched and buffered in the channel subsystem.

The same actions for signaling errors and terminating operations take place when unlimited prefetching is allowed by the ORB as when it is not allowed. However, when unlimited prefetching is specified and an error condition is detected, both the channel subsystem and the program must recognize that the points of termination at the channel subsystem and at the I/O device may be different in terms of the channel command in execution at the point of error. The channel subsystem indicates the point of termination at the channel subsystem by storing the appropriate CCW address in word 1 of the sub-channel-status word and the point of termination at the device by storing the secondary-CCW address in word 4 of the format-0 extended-status word.

When prefetching has been specified in the ORB, the result of modifications to CCWs after START SUBCHANNEL has been executed or after self-describing channel programs have been used is unpredictable. (See note 2 for the definition of self-describing channel programs.)

2. Data chaining may be used to rearrange information as it is transferred between main storage and an I/O device. Data chaining permits blocks of information to be transferred to or from non-

contiguous areas of storage, and, when used in conjunction with the skipping function, data chaining allows the program to place in main storage specified portions of a block of data.

When, during an input operation, the program specifies data chaining to a location in which data has been placed under the control of the current CCW, the channel subsystem, in fetching the next CCW, fetches the new contents of the location. This is true even if the location contains the last byte transferred under the control of the current CCW. When a channel program data-chains to a CCW placed in storage by the CCW specifying data chaining, the input block is said to be self-describing. A self-describing block contains one or more CCWs that designate storage locations and counts for subsequent data in the same input block.

The use of self-describing blocks is equivalent to the use of unchecked data. An I/O data-transfer malfunction that affects validity of a block of information is signaled only at the completion of data transfer. The error condition normally does not prematurely terminate or otherwise affect the performance of the operation. Thus, there is no assurance that a CCW read as data is valid until the operation is completed. If the CCW thus read is in error, use of the CCW in the current operation may cause subsequent data to be placed at wrong locations in main storage with resultant destruction of its contents, subject only to the control of the protection key and the address-limit-checking facility, if used.

3. When, during data chaining, a device transfers data by using the data-streaming feature, an overrun or chaining-check condition may be recognized when a small byte-count value is specified in the CCW. The minimum acceptable number of bytes that can be specified varies as a function of the system model and system activity.

## Command Chaining

During command chaining, the new CCW fetched by the channel subsystem specifies a new I/O operation. The channel subsystem fetches the new CCW upon the receipt of the device-end signal for the current operation. If the new CCW does not have its S flag set to one and no unusual conditions are detected, the channel subsystem initiates the new operation. The presence of the S flag set to one or unusual conditions causes command chaining to be

suppressed. When command chaining takes place, the completion of the current operation does not cause an I/O interruption, and the count indicating the amount of data transferred during the current operation is not made available to the program. For operations involving data transfer, the new command always applies to the next block of data at the device.

Command chaining takes place and the new operation is initiated only if no unusual conditions have been detected in the current operation. In particular, the channel subsystem initiates a new I/O operation by command chaining upon receipt of a status byte containing only the following bit combinations: (1) device end, (2) device end and status modifier, (3) device end and channel end, and (4) device end, channel end, and status modifier. In the first two cases, channel end is signaled before device end, with all other status bits zeros. If a condition such as attention, unit check, unit exception, incorrect length, program check, or protection check has occurred, the sequence of operations is concluded, and the status associated with the current operation causes an interruption condition to be generated. The new CCW in this case is not fetched. The incorrect-length condition does not suppress command chaining if the current CCW has the SLI flag set to one.

An exception to sequential chaining of CCWs occurs when the I/O device presents the status-modifier condition with the device-end signal or channel-end and device-end signals. When command chaining is specified and no unusual conditions have been detected, or when command retry has been previously signaled and an immediate retry could not be performed, the combination of status-modifier and device-end bits causes the channel subsystem to alter the sequential execution of CCWs. If command chaining was specified, status modifier and device end cause the channel subsystem to fetch and chain to the CCW whose main-storage address is 16 higher than that of the CCW that specified chaining. If command retry was previously signaled and immediate retry could not be performed, the status causes the channel subsystem to command chain to the CCW whose storage address is 8 higher than that of the CCW for which retry was initially signaled.

When both command and data chaining are specified, the first CCW associated with the operation specifies the operation to be performed, and the last CCW specifies whether another operation follows.

**Programming Note:** Command chaining makes it possible for the program to initiate transfer of multiple blocks of data by issuing a single START SUBCHANNEL instruction. It also permits a subchannel to be set for execution of other commands, such as positioning the disk-access mechanism, and for data-transfer operations without interference by the program at the end of each operation. Command chaining, in conjunction with the status-modifier condition, permits the channel subsystem to modify the normal sequence of operations in response to signals provided by the I/O device.

## Skippping

Skipping causes the suppression of main-storage references during an I/O operation. It is defined only for read, read-backward, sense-ID, and sense operations, and is controlled by the skip flag, which can be specified individually for each CCW. When the skip flag is one, skipping occurs; when it is zero, normal operation takes place. The setting of the skip flag is ignored in all other operations.

Skipping affects only the handling of information by the channel subsystem. The operation at the I/O device proceeds normally, and information is transferred. The channel subsystem keeps updating the count but does not place the information in main storage. Chaining is not precluded by skipping. In the case of data chaining, normal operation is resumed if the skip flag in the new CCW is zero.

No checking for invalid or protected data addresses takes place during skipping.

**Programming Note:** Skipping, when combined with data chaining, permits the program to place in main storage specified portions of a block of information from an I/O device.

## Program-Controlled Interruption

The program-controlled-interruption (PCI) function permits the program to cause an I/O interruption during the performance of an I/O operation. The function is controlled by the PCI flag of the CCW. Neither the value of the PCI flag nor the associated interruption request affects the performance of the current operation.

The value of the PCI flag can be one either in the first CCW designated for the current start or resume function or in a CCW fetched during chaining. If the PCI flag is one in a CCW that has become current, the subchannel becomes status pending with intermediate status, and an I/O-interruption request is generated. The point at which the subchannel becomes status pending depends on the progress of the current start or resume function as follows:

1. If the PCI flag is one in the first CCW associated with a start function or a resume function, the subchannel becomes status pending with intermediate status only after the command has been accepted.
2. If the PCI flag is one in a CCW that has become current while data chaining, the subchannel becomes status pending with intermediate status after all data designated by the preceding CCW has been transferred.
3. If the PCI flag is one in a CCW that has become current while command chaining, the subchannel becomes status pending with intermediate status as that CCW becomes current.

In all cases, if the subchannel is enabled for I/O interruptions, the point of interruption depends on the current activity in the system and may be delayed. No predictable relationship exists between the point at which the interruption request is generated because of the PCI flag and the extent to which data transfer has been completed to or from the area designated by the CCW. However, all the fields within the SCSW pertain to the same instant.

An intermediate interruption condition that is made pending because of a PCI flag remains pending during chaining if not cleared by TEST SUBCHANNEL or CLEAR SUBCHANNEL. If another CCW containing a PCI flag that is one becomes current prior to the clearing of the intermediate interruption condition, only one interruption condition is preserved.

An intermediate interruption may occur while the subchannel is subchannel-and-device active with the operation specified by the CCW causing the intermediate interruption condition or with the operation specified by a CCW that has subsequently become current. If the intermediate interruption condition is not cleared prior to the conclusion of the operation or chain of operations, the condition is indicated together with the primary interruption condition at the

conclusion of the operation or chain of operations. The intermediate interruption condition may be cleared by TEST SUBCHANNEL while the subchannel is subchannel active.

If the SCSW stored by TEST SUBCHANNEL indicates that the subchannel is status pending with intermediate status and the operation or chain of operations has not been concluded (that is, the activity-control field indicates subchannel-and-device active or suspended), then the CCW-address field contains an address that is 8 higher than the address of the most recent CCW to become current and have a PCI flag that is one, or the CCW-address field contains an address that is 8 higher than the address of a CCW that has subsequently become current. Unless the SCSW also contains the primary-status bit set to one, the device-status field contains zeros, and the count is unpredictable.

Subchannel-status conditions other than PCI may be indicated when the SCSW is stored. If the subchannel is not also status pending with primary status, these conditions may or may not be indicated again. If the subchannel-status condition is detected while prefetching and the operation or chain of operations is concluded before the condition affects an operation, the condition is reset and is not indicated when the subchannel subsequently becomes status pending with primary status. If the subchannel-status condition affects an operation, the condition is indicated when the subchannel becomes status pending with primary status.

If the program-controlled-interruption condition remains pending until the operation or chain of operations is concluded at the subchannel, a single interruption request exists. When TEST SUBCHANNEL is subsequently executed, the status-control field of the SCSW stored indicates both the primary interruption condition and the intermediate interruption condition, and the PCI bit of the subchannel-status field is one.

The value of the PCI flag is inspected in every CCW except for those CCWs that specify the transfer-in-channel command. The PCI flag is ignored during initial program loading.

#### **Programming Notes:**

1. The program-controlled interruption provides a means of alerting the program to the progress of

chaining during an I/O operation. It permits programmed dynamic main-storage allocation.

2. A CCW with a PCI flag set to one may, if retried because of command retry, cause multiple PCI interruptions to occur. (See "Command Retry" on page 15-42.)

## **CCW Indirect Data Addressing**

CCW indirect data addressing permits a single channel-command word to control the transfer of data that spans noncontiguous 2K-byte or 4K-byte blocks in main storage. The use of CCW indirect data addressing also allows the program to designate data addresses above 16M bytes when using format-0 CCWs or above 2G bytes when using format-1 CCWs. CCW indirect data addressing is specified by a flag in the CCW which, when one, indicates that the data address is not used to directly address data. Instead, the address points to a list of words or doublewords, called indirect-data-address words (IDAWs), each of which contains an absolute address designating a data area in main storage.

IDAWs have either of two formats, called format 1 and format 2, as determined by the format-2-IDAW control, bit 14 of word 1 of the ORB associated with the channel program being executed. When the format-2-IDAW control is zero, the IDAW is format 1 and is a word containing a 31-bit address. When the control is one, the IDAW is format 2 and is a doubleword containing a 64-bit address. The IDAW formats are as follows:

#### **Format-1 IDAW**

0	Data Address
0	31

#### **Format-2 IDAW**

Data Address (Bytes 0-3)	
0	31
Data Address (Bytes 4-7)	
32	63

Bit 0 (format 1) is reserved for future use and must be zero; otherwise, a program-check condition may be recognized, as described below.

A format-1 IDAW designates a data area within a 2K-byte block of main storage and is capable of addressing storage in the range of 0 to  $2^{31} - 1$ .

A format-2 IDAW designates a data area within a 2K-byte or 4K-byte block of main storage, as determined by the 2K-IDAW control, bit 15 of word 1 of the ORB associated with the channel program being executed, and is capable of addressing storage in the range of 0 to  $2^{64} - 1$ . When the 2K-IDAW-control bit is zero, each format-2 IDAW of the designated channel program designates a 4K-byte block of main storage. When the 2K-IDAW-control bit is one, each format-2 IDAW designates a 2K-byte data-area block. All IDAWs associated with the designated channel program must have the same IDAW format, and all of those IDAWs specify the same size of storage block.

When the indirect-data-addressing bit in the CCW is one, the data-address field of the CCW designates the location of the first IDAW to be used for data transfer for the command. Additional IDAWs, if needed for completing the data transfer for the CCW, are in successive locations in storage. The number of IDAWs required for a CCW is determined by the IDAW format as specified in the ORB, by the count field of the CCW, and by the data address in the initial IDAW. When, for example, (1) the ORB specifies format-2 IDAWs with 4K-byte blocks, (2) the CCW count field specifies 8K bytes, and (3) the first IDAW designates a location in the middle of a 4K-byte block, then three IDAWs are required.

The IDAW designated by the CCW can designate any location. Data is then transferred, for read, write, control, sense ID, and sense commands, to or from successively higher storage locations or, for a read-backward command, to successively lower storage locations, until a 2K-byte block boundary (format-1 or format-2 IDAW) or a 4K-byte block boundary (format-2 IDAW) is reached. The control of data transfer is then passed to the next IDAW. The second and any subsequent IDAWs must designate, depending on the command, the first byte, or the last byte for read backward, of a 2K-byte block (format-1 or format-2 IDAW) or a 4K-byte block (format-2 IDAW). Thus, for read, write, control, sense ID, and sense commands, such format-1 IDAWs must have zeros in bit positions 21-31, and such format-2 IDAWs must have zeros in bit positions 53-63 (2K-byte blocks) or 52-63 (4K-byte blocks). For a read-backward command, such format-1 IDAWs must have ones in bit positions 21-31, and such format-2 IDAWs must have ones in bit positions 53-63 (2K-byte blocks) or 52-63 (4K-byte blocks). If any of these rules is violated, a program-check condition is recognized.

Except for the unique restrictions on the designation of the data address by the IDAW, all other actions taken for the data address, such as for protected storage and invalid addresses, and the actions taken for data prefetching are the same as when indirect data addressing is not used.

IDAWs pertaining to the current CCW or a prefetched CCW may be prefetched. The number of IDAWs that can be prefetched cannot exceed that required to satisfy the count in the CCW that points to the IDAWs. An IDAW takes control of data transfer when the last byte has been transferred for the previous IDAW. The same actions take place as with data chaining regarding when an IDAW takes control of data transfer during an I/O operation. That is, when the count for the CCW has not reached zero, a new IDAW takes control of the data transfer when the last byte has been transferred for the previous IDAW for that CCW, even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end, and status modifier are received prior to the transfer of any data bytes pertaining to the new IDAW.

A prefetched IDAW does not take control of an I/O operation if the count in the CCW has reached zero with the transfer of the last byte of data for the previous IDAW for that CCW. Program or access errors detected in prefetched IDAWs are not indicated to the program until the IDAW takes control of data transfer. However, when the channel subsystem detects an invalid CBC on the contents of a prefetched IDAW or its associated key, the condition may be indicated to the program, when detected, before the IDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of an IDAW or its associated key, see "Channel-Control Check" on page 16-28.

Bits 1-31 (format 1) or bits 0-63 (format 2) designate the absolute storage location of the first byte to be used in the data transfer. When format-1 IDAWs are specified, the channel subsystem forms a 64-bit absolute main-storage address by appending 33 zero bits on the left of bit 1.

When the IDAW flag of the CCW is set to one and any of the following conditions occurs:

1. Format-1 IDAWs are specified in the ORB, and the address in the CCW does not designate the first IDAW on a word boundary,

2. Format-2 IDAWs are specified in the ORB, and the address in the CCW does not designate the first IDAW on a doubleword boundary,
3. The address in the CCW designates a storage location that is not physically available,
4. Access to the storage location specified by the address in the CCW is prohibited by protection, or
5. Bit 0 (format 1 only) of the first IDAW is not zero,

then, depending on the model, one of the following two actions is taken independent of the setting of the skip flag (if condition 5 above is true, action 2 must be taken).

1. The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.
2. The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and the status presented by the device.

## Modified CCW Indirect Data Addressing

Modified CCW indirect data addressing (MIDA) permits a single channel-command word to control the transfer of up to 65,535 bytes of data that spans non-contiguous blocks in main storage. Each block of main storage to be transferred may be specified on any boundary and length up to 4K bytes, provided the specified block does not cross a 4K-byte boundary. The use of modified CCW indirect data addressing requires that the program designate 64-bit data addresses.

Modified CCW indirect data addressing is controlled by a flag in the ORB and specified by a flag in the CCW which, when both are one, indicates that the CCW data address is not used to directly address data. Instead, the address points to a contiguous list of up to 256 quadwords called modified-indirect-data-

address words (MIDAWs), each of which contains flags, a byte count, and a 64-bit address designating a data area in absolute storage.

Use of modified CCW indirect data addressing may be restricted to certain channel-path types. If the MIDA flag in the CCW is one, specifying the use of modified CCW indirect data addressing, and the sub-channel is associated with channel paths that do not support modified CCW indirect data addressing, a program check is recognized.

The MIDAW begins on a quadword boundary and has the following format:

**Doubleword**

0	Reserved	Flags	Count
1	Data Address		

0                          40                          48                          63

*Figure 15-7. Modified-Indirect-Data-Address Word (MIDAW)*

**Reserved :** Bits 0-39 of the MIDAW are reserved for future use and must be zero; otherwise, a program-check condition may be recognized.

**Flags :** Bits 40-47 of the MIDAW contain an 8-bit flag field. The meaning of each flag bit is as follows. Bits not shown are reserved.

### Bit Meaning

40 Last MIDAW: Bit 40, when one, specifies that the MIDAW is the last in the contiguous list of MIDAWs.

41 Skip: Bit 41, when one, specifies the suppression of transfer of information to main storage during a read, read-backward, sense ID, or sense operation, thus specifying that skipping is in effect. When the operation is not read, read-backward, sense ID, or sense, bit 41 is ignored and skipping is not in effect

When skipping is in effect, no checking for invalid or protected data addresses takes place.

42 Data-transfer-interruption control: Bit 42, when one, specifies that a program-check be recognized when the device attempts to transfer data.

**Count :** Bits 48-63 of the MIDAW specify the number of bytes in the storage area designated by the data-address field. The count value must not be zero;

otherwise a program-check condition is recognized. When skipping is in effect, the count value may in the range of 1 - 65,535. When skipping is not effect, the count value, in conjunction with the data address, must not specify the transfer of data that crosses a 4K-block boundary; otherwise, a program-check condition is recognized. When the count value causes the total data transfer count to exceed that specified in the CCW count field, a program-check condition is recognized.

**Data Address :** Bits 64-127 of the MIDAW designate the 64-bit address of a location in absolute storage which is the first byte of information to be transferred. If the count field specifies zero, this field is not checked.

When modified CCW indirect data addressing is specified, the data-address field of the CCW designates the location of the first MIDAW to be used for data transfer for the CCW command. Additional MIDAWs, if needed for completing the data transfer for the CCW, are fetched from successive locations in storage. The number of MIDAWs required for a CCW is determined by the count field of the CCW in relation to the count fields in the list of MIDAWs designated by the CCW. The list must not cross a 4K-byte boundary.

If a list of two or more MIDAWs is designated for a read operation, it is unpredictable in which order the MIDAW data addresses are used to transfer information into main storage. Thus, if two or more MIDAWs in a MIDAW list designate overlapping storage areas, the results are unpredictable.

MIDAWs that specify the transfer of data (MIDAWs for which skipping is not in effect) may specify a transfer count in the range of 1 - 4096 bytes, provided the MIDAW does not specify a data transfer that crosses a 4K-byte boundary; MIDAWs that specify the suppression of the transfer of data (MIDAWs for which skipping is in effect) may specify a skip count in the range of 1 - 65,535 bytes. The total number of bytes that can be transferred or skipped or both by a single MIDAW list is limited by the CCW count field, which is a maximum of 65,535 bytes. The sum of the count fields in all of the MIDAWs in the list designated by the CCW should equal the value in the count field of the CCW; otherwise, a program-check condition may be recognized.

The MIDAW designated by the CCW can designate any location. When the MIDAW skip flag is zero and

the CCW specifies the read, write, control, sense ID, or sense command, data is then transferred to or from successively higher storage locations until the number of bytes specified by the MIDAW count field have been transferred. When the MIDAW skip flag is zero and the CCW specifies the read backwards command, data is then transferred to successively lower storage locations until the number of bytes specified by the MIDAW count field have been transferred. When the MIDAW skip flag is one and the CCW specifies the read, sense ID, or sense command, skipping occurs to successively higher storage locations until the number of bytes specified by the MIDAW count field have been skipped. When the MIDAW skip flag is one and the CCW specifies the read backwards command, skipping occurs to successively lower storage locations until the number of bytes specified by the MIDAW count field have been skipped.

When the specified number of bytes have been transferred or skipped and the CCW specifies a subsequent MIDAW, the control of data transfer is then passed to the next MIDAW in the list. Like the MIDAW designated by the CCW, subsequent MIDAWs may designate any location and any length, provided the MIDAW does not specify a data transfer that crosses a 4K-byte boundary; otherwise, a program-check condition is recognized.

Except for the unique restriction on designating a valid combination of data address and count by a MIDAW and the resulting behavior when the data-transfer-interruption control is one, all other actions taken for data addresses specified by a MIDAW, such as for protected storage and invalid addresses, and the actions taken for data prefetching, are the same as when modified CCW indirect data addressing is not used.

MIDAWs pertaining to the current CCW or a prefetched CCW may be prefetched. The number of MIDAWs that can be prefetched cannot exceed that required to satisfy the count in the CCW that designates the MIDAWs. Any MIDAWs that are prefetched for a CCW and are not used are discarded.

Similar to when CCW data chaining occurs, the action of transferring control from one MIDAW to the next is transparent to any attached device. A MIDAW takes control of data transfer when the last byte specified by the previous MIDAW has been transferred, even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end,

and status modifier are received prior to the transfer of any data bytes pertaining to the new MIDAW.

A prefetched MIDAW does not take control of an I/O operation if the count in the CCW has reached zero with the transfer of the last byte of data for the previous MIDAW. Program or access errors detected in prefetched MIDAWs are not indicated to the program until the MIDAW takes control of data transfer, even if an attempt had been made to prefetch that data. However, when the channel subsystem detects an invalid CBC on the contents of a prefetched MIDAW or its associated key, the condition may be indicated to the program, when detected, before the MIDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of a MIDAW or its associated key, see "Channel-Control Check" on page 16-28.

When a CCW specifies a MIDAW list and either the address in the CCW designates a storage location that is not physically available or the address designates a storage location to which access is prohibited by protection, then, depending on the model, one of the following two actions is taken:

- The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.
- The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and the status presented by the device.

## Suspension of Channel-Program Execution

The suspend function, when used in conjunction with RESUME SUBCHANNEL, provides the program with a means to stop and restart the execution of a channel program. The initiation of the suspend function is controlled by the setting of the suspend control, bit 4 of word 1 of the ORB. The suspend function is signaled when suspend control has been specified for the subchannel in the ORB and a CCW containing an

S flag set to one becomes the current CCW. The flag can be indicated either in the first CCW of the channel program or in a CCW fetched while command chaining. The S flag is not valid and causes a program-check condition to be recognized if (1) the ORB contains the suspend-control bit set to zero, or (2) the CCW is fetched while data chaining (see "Data Chaining" on page 15-31, concerning the handling of programming errors detected during data chaining).

Upon recognition of the suspend function, suspension of channel-program execution occurs when the CCW becomes current (see "Channel-Command Word" on page 15-26, for a definition of when a CCW becomes current). If suspension occurs during command chaining, the device is signaled that command chaining is no longer in effect.

RESUME SUBCHANNEL signals that the CCW that caused channel-program suspension may have been modified, that the CCW must be refetched, and that the contents of the CCW must be examined to determine the settings of the flags. If the S flag is one, execution of that CCW does not occur. If the CCW is valid and the S flag in the CCW is zero, execution is initiated (see "RESUME SUBCHANNEL" on page 14-10 and "Start Function and Resume Function" on page 15-18).

When a valid CCW that contains an S flag validly set to one becomes the current CCW during command chaining and the resume-pending condition is not recognized, the suspend function is performed and causes the following actions to occur in the order given:

1. The device is signaled that the chain of operations has been concluded.
2. Channel-program execution is suspended at the subchannel; all prefetched IDAWs, MIDAWs, CCWs, and data are discarded; and the subchannel is set up such that the resume function can be performed when the subchannel is next recognized to be resume pending.
3. If the measurement-block-update mode is active and the subchannel is enabled for the mode, the accrued values of the measurement data, including the start-subchannel and sample count, are added to the accumulated values in the measurement block for the subchannel. The start-subchannel count is the only measurement data that is updated in the measurement block if the

channel-subsystem-timing facility is not available for the subchannel. (See “Channel-Subsystem Monitoring” on page 17-1 for more information.)

If a measurement-check condition is detected during the measurement-block update, the channel program is terminated at the subchannel. The subchannel is made status pending with primary, secondary, and alert status, the device-status and subchannel-status fields are set to zero, and one of the measurement-check conditions is indicated in the extended-status flags of the format-0 ESW. The subchannel is not placed in the suspended state. (See “Subchannel-Control Field” on page 16-11.)

4. The subchannel is placed in the suspended state.
5. If the subchannel is not resume pending at this point, the intermediate interruption condition due to suspension is recognized if the suppress-suspended-interruption bit of the ORB is zero; otherwise, the resume function is performed.

When a valid CCW that contains an S flag validly set to one becomes the current CCW during command chaining and the resume-pending condition is recognized, the resume function is performed instead of the suspend function.

When the first CCW of a channel program contains an S flag validly set to one and the resume-pending condition is not recognized, the suspend function is performed and causes the following actions to occur in the order given:

1. Channel-program execution is suspended prior to the selection of the device.
2. The subchannel is set up such that the resume function can be performed when the subchannel is next recognized to be resume pending.
3. If the measurement-block-update mode is active and the subchannel is enabled for the mode, the SSCH+RSCH count is incremented, and the accrued function-pending time (a function of the setting of the timing-facility bit) is added to the accumulated value in the measurement block for the subchannel.

If a measurement-check condition is detected during the measurement-block update, the channel program is not started at the subchannel. The subchannel is made status pending with primary,

secondary, and alert status. Deferred condition code one is set, and the start-pending bit remains set to one. The device-status and subchannel-status fields are set to zero, and one of the measurement-check conditions is indicated in the extended-status flags of the format-0 ESW. The subchannel is not placed in the suspended state. (See “Subchannel-Control Field” on page 16-11.)

4. The subchannel is placed in the suspended state.
5. If the subchannel is not resume pending at this point, the subchannel is made status pending with intermediate status due to suspension if the suppress-suspended-interruption-control bit of the ORB is zero; otherwise, the resume function is performed.

When the first CCW of a channel program contains an S flag validly set to one and the resume-pending condition is recognized, the resume function is performed instead of the suspend function.

#### **Programming Notes:**

1. The execution of MODIFY SUBCHANNEL and START SUBCHANNEL completes with condition code 2 set if the designated subchannel is suspended. The start function is indicated at the subchannel while the subchannel is in the suspended state.
2. In certain situations, normal resumption of the execution of a channel program that has been suspended may not be desired. Normal termination of the suspended channel-program execution may be accomplished by:
  - a. Executing HALT SUBCHANNEL and designating the subchannel.
  - b. Modifying the CCWs in storage such that, when channel-program execution is resumed, the command transferred to the device is a control command with all modifier bits specified as zeros (no-operation) and with the chain-command flag specified as zero; and then executing RESUME SUBCHANNEL.
- c. When an IRB indicates measurement check along with zero device status, zero subchannel status, and status pending with primary, secondary, and alert status, it may indicate

that the measurement check was detected during an attempt to place the subchannel into the suspended state.

3. If the suspended interruption is suppressed, the N condition and DCTI values applicable to the preceding subchannel-active period are not made available to the program. The execution of RESUME SUBCHANNEL when the subchannel is in the suspended state causes path-not-operational conditions and the N condition to be reset to zeros. Path-not-operational conditions and the N condition are not reset when RESUME SUBCHANNEL is executed and the designated subchannel is not in the suspended state.

## Commands and Flags

Figure 15-8 on page 15-41 lists the command codes for the seven commands and indicates which flags are defined for each command. Except for a format-1 CCW specifying transfer in channel, the flags are ignored for all commands for which they are not defined. The flags are reserved in a format-1 CCW specifying transfer in channel and must be zeros.

Name	Code	Flags
Write	M M M M M M 0 1	CD CC SLI PCI IDA MIDA
Read	M M M M M M 1 0	CD CC SLI SK PCI IDA MIDA
Read backward	M M M M 1 1 0 0	CD CC SLI SK PCI IDA MIDA
Control	M M M M M M 1 1	CD CC SLI PCI IDA MIDA
Sense	M M M M 0 1 0 0	CD CC SLI SK PCI IDA MIDA
Sense ID	1 1 1 0 0 1 0 0	CD CC SLI SK PCI IDA MIDA
Transfer in Channel	X X X X 1 0 0 0	(See note below)

### Explanation:

CC	Chain command
CD	Chain data
IDA	Indirect data addressing
M	Modifier bit
MIDA	Modified indirect data addressing
PCI	Program-controlled interruption
S	Suspend
SK	Skip
SLI	Suppress-length indication
X	Ignored in a format-0 CCW; must be zero in a format-1 CCW
Note:	Flags are ignored in a format-0 transfer-in-channel CCW and must be zeros in a format-1 transfer-in-channel CCW.

Figure 15-8. Command Codes and Flags

All flags have individual significance, except for the following cases:

- The CC and SLI flags are ignored when the CD flag is set to one, and, for output forward operations the SK flag is ignored.
- The presence of the SLI flag is ignored for immediate operations involving format-0 CCWs, in which case the incorrect-length indication is suppressed regardless of the setting of the flag.
- The incorrect-length indication may be suppressed for immediate operations when executing a format-1 CCW, depending on the incorrect-length-suppression mode.
- The PCI flag is ignored during initial program loading. All flags, except the PCI flag, are ignored when the S flag is one.
- The MIDA flag is mutually exclusive from both the IDA and SKP flags. If the IDA or SKP flag is specified and the MIDA flag is specified, a program-check condition is recognized.

### Programming Notes:

1. A malfunction that affects the validity of data transferred in an I/O operation is signaled at the end of the operation by means of unit check or channel-data check, depending on whether the device (control unit) or the channel subsystem detected the error. In order to make use of the checking facilities provided in the system, data read in an input operation should not be used until the end of the operation has been reached and the validity of the data has been checked. Similarly, on writing, the copy of data in main storage should not be destroyed until the program has verified that no malfunction affecting the transfer and recording of data was detected.
2. An error condition may be recognized and the I/O operation terminated when 256 or more chained commands are executed with a device and none of the executed commands result in the transfer of any data. When this condition is recognized, program check is indicated.
3. All CCWs that require suppression of incorrect-length indications must use the SLI flag.

## Branching in Channel Programs

The channel subsystem provides two methods to modify the normal sequential execution of the CCWs in a channel program. One is the transfer-in-channel

(TIC) command (described in “Transfer in Channel” on page 15-42), which can be used to loop back to a previously executed CCW, or to connect discontiguous segments of the channel program. The other method, which uses the status-modifier device-status bit (described in the publication *ESA/390 Common I/O-Device Commands*, SA22-7204), allows conditions at the device to cause the channel to bypass the next CCW in the channel program.

## Transfer in Channel

### Format-0 TIC CCW

1 0 0 0	CCW Address
0	8
32	63

### Format-1 TIC CCW

0 0 0 1 0 0 0	Zeros
0	8
32	63

The next CCW is fetched from the location in absolute main storage designated by the data-address field of the CCW specifying transfer in channel. The transfer-in-channel command does not initiate any I/O operation, and the I/O device is not signaled of the execution of the command. The purpose of the transfer-in-channel command is to provide chaining between CCWs not located in adjacent doubleword locations in an ascending order of addresses. The command can occur in both data and command chaining.

Bits 29-31 (format 0) or bits 61-63 (format 1) of a CCW that specifies the transfer-in-channel command must be zeros, designating a CCW on a doubleword boundary. Furthermore, a CCW specifying transfer in channel may not be fetched from a location designated by an immediately preceding transfer in channel. When either of these errors is detected or when an invalid address is designated in the transfer-in-channel command, the program-check condition is generated. When a CCW that specifies the transfer-in-channel command designates a CCW at a location protected against fetching, the protection-check condition is generated. Detection of these errors during data chaining causes the operation at the I/O device to be terminated and an interruption condition to be

generated, while during command chaining it causes only an interruption condition to be generated.

The contents of the second half of the format-0 CCW, bit positions 32-63, are ignored. Similarly, the contents of bit positions 0-3 of the format-0 CCW are ignored.

Bit positions 0-3 and 8-32 of the format-1 CCW must contain zeros; otherwise, a program-check condition is generated.

## Command Retry

The channel subsystem has the capability to perform command retry, a procedure that causes a command to be retried without requiring an I/O interruption. This retry is initiated by the control unit presenting either of two status-bit combinations by means of a special sequence. When immediate retry can be performed, it presents a channel-end, unit-check, and status-modifier status-bit combination, together with device end. When immediate retry cannot be performed, the presentation of device end is delayed until the control unit is prepared. When device end is presented alone, the previous command is transferred again. If device end is accompanied by status modifier, command retry is not performed, and the channel subsystem command-chains to the CCW following the one for which command retry was signaled (for information on status modifier, see the publication *ESA/390 Common I/O-Device Commands*, SA22-7204). When the channel subsystem is not capable of performing command retry due to an error condition, or when any status bit other than device end or device end and status modifier accompanies the requested command-retry initiation, the retry is suppressed, and the subchannel becomes status pending. The SCSW stored by TEST SUBCHANNEL contains the status provided by the I/O device.

**Programming Note:** The following possible results of a command retry must be anticipated by the program:

1. A CCW containing a PCI may, if retried because of command retry, cause multiple PCI interruptions to occur.
2. If a CCW used in an operation is changed before that operation has been successfully completed, the results are unpredictable.

---

## Concluding I/O Operations before Initiation

Subsequent to the execution of START SUBCHANNEL or RESUME SUBCHANNEL and before the first command is accepted, the start function can be ended at the subchannel by CANCEL SUBCHANNEL (if the instruction is installed), CLEAR SUBCHANNEL, or HALT SUBCHANNEL. If the I/O operation is ended by CANCEL SUBCHANNEL, there is no subsequent interruption condition from the I/O operation, and the subchannel is available for the initiation of another start function. However, the device may have signaled a busy condition while the canceled operation was start pending. In this case, the device owes a no-longer-busy signal to the channel subsystem. This may result in unsolicited device-end status before the next operation is initiated at the device. (See also "Clear Function" on page 15-13 and "Halt Function" on page 15-15.)

---

## Concluding I/O Operations during Initiation

After the designated subchannel has been determined to be in a state such that START SUBCHANNEL can be executed, certain tests are performed on the validity of the information specified by the program and on the logical availability of the associated device. This testing occurs during or subsequent to the execution of START SUBCHANNEL and during command chaining and command retry.

A data-transfer operation is initiated at the subchannel and device only when no programming or equipment errors are detected by the channel subsystem and when the device responds with zero status during the initiation sequence. When the channel subsystem detects or the device signals any unusual condition during the initiation of an I/O operation, the command is said to be not accepted. In this case, the subchannel becomes status pending with primary, secondary, and alert status. Deferred condition code 1 is set, and the start-pending bit remains set to one.

Conditions that preclude the initiation of an I/O operation are detailed in the SCSW stored by TEST SUBCHANNEL. In this situation, the device is not started, no interruption conditions are generated subsequent

to TEST SUBCHANNEL, and the subchannel is idle. The device is immediately available for the initiation of another operation, provided the command was not rejected because of the busy or not-operational condition.

When an unusual condition causes a command to be not accepted during the initiation of an I/O operation by command chaining or command retry, an interruption condition is generated, and the subchannel becomes status pending with combinations of primary, secondary, and alert status as a function of the status signaled by the device. The status describing the condition remains at the subchannel until cleared by TEST SUBCHANNEL. The conditions are indicated to the program by means of the corresponding status bits in the SCSW. A path-not-operational condition recognized during command chaining is signaled to the program by means of an interface-control-check indication. The new I/O operation at the device is not started.

START SUBCHANNEL is executed independent of its associated device. Tests on most program-specified information, on device availability and unit status, and on most error conditions are performed subsequent to the execution of START SUBCHANNEL. When any conditions are detected that preclude the performance of the start function, an interruption condition is generated by the channel subsystem and placed at the subchannel, causing it to become status pending.

---

## Immediate Conclusion of I/O Operations

During the initiation of an I/O operation, the device can accept the command and signal the channel-end condition immediately upon receipt of the command code. An I/O operation causing the channel-end condition to be signaled during the initiation sequence is called an *immediate operation*. Status generated by the device for the immediate command, when command chaining is not specified and command retry is not signaled, causes the subchannel to become status pending with combinations of primary, secondary, intermediate, and alert status as a result of information specified in the ORB and CCW and status presented by the device. If the immediate operation is the first operation of the channel program, deferred condition code 1 is set and accompanies the status

indications. If intermediate status is indicated, the indication can occur only as a result of the CCW having the PCI flag set to one (see “Program-Controlled Interruption” on page 15-34).

Whenever command chaining is specified after an immediate operation and no unusual conditions have been detected during the operation, or when command retry occurs for an immediate operation, an interruption condition is not generated. The subsequent commands in the chain are handled normally, and, usually, the channel-end condition for the last CCW generates a primary interruption condition. If device end is signaled with channel end, a secondary interruption condition is also generated.

Whenever immediate completion of an I/O operation is signaled, no data has been transferred to or from the device, and the data address in the CCW is not checked for validity. If the subchannel is in the incorrect-length-suppression mode, incorrect length is not indicated to the program, and command chaining is performed when specified. If the subchannel is in the incorrect-length-indication mode, incorrect length and command chaining are under control of the SLI and chain-command flags. The conditions that cause the incorrect-length indication to be suppressed are summarized in Figure 15-6 on page 15-31.

**Programming Note:** I/O operations for which the entire operation is specified in the command code may be performed as immediate operations. Whether the command is executed as an immediate operation depends on the operation and type of device.

---

## Concluding I/O Operations During Data Transfer

When the subchannel has been passed the contents of an ORB, the subchannel is said to be start pending. When the I/O operation has been initiated and the command has been accepted, the subchannel becomes subchannel-and-device active and remains in that state unless (1) the channel subsystem detects an equipment malfunction, (2) the operation is concluded by the execution of CLEAR SUBCHANNEL or HALT SUBCHANNEL, or (3) status that causes a primary interruption condition to be recognized (usually channel end) is accepted from the device. When command chaining and command retry are not specified or when chaining is sup-

pressed because of unusual conditions, the status that is recognized as primary status causes the operation at the subchannel to be concluded and an interruption condition to be generated. The status bits in the associated SCSW indicate primary status and the unusual conditions, if any. The device can present status that is recognized as primary status at any time after the initiation of the I/O operation, and the presentation of status may occur before any data has been transferred.

For operations not involving data transfer, the device normally controls the timing of the channel-end condition. The duration of data-transfer operations may be variable and may be controlled by the device or the channel subsystem.

Excluding equipment errors and the execution of the CLEAR SUBCHANNEL, HALT SUBCHANNEL, and RESET CHANNEL PATH instructions, the channel subsystem signals the device to conclude the performance of an I/O operation during data transfer whenever any of the following conditions occurs:

- The storage areas designated for the operation are exhausted or filled.
- A program-check condition is detected.
- A protection-check condition is detected.
- A chaining-check condition is detected.
- A channel-control-check condition is detected that does not affect the control of the I/O operation.

The first of these conditions occurs when the channel subsystem has decremented the count to zero in the last CCW associated with the operation. A count of zero indicates that the channel subsystem has transferred all information specified by the I/O operation. The other four conditions are due to errors and cause premature conclusion of data transfer. In either case, the conclusion is signaled in response to a service request from the device and causes data transfer to cease. If the device has no blocks defined for the operation (such as writing on magnetic tape), it concludes the operation and presents channel-end status.

The device can control the duration of an operation and the timing of channel end by blocking of data. On certain operations for which blocks are defined (such as reading on magnetic tape), the device does not

present channel-end status until the end of the block is reached, regardless of whether the device has been previously signaled to conclude data transfer.

Checking for the validity of the data address is performed only as data is transferred to or from main storage. When the initial data address in the CCW is invalid, no data is transferred during the operation, and the device is signaled to conclude the operation in response to the first service request. On writing, devices such as magnetic-tape units request the first byte of data before any mechanical motion is started, and, if the initial data address is invalid, the operation is terminated by the channel subsystem before the recording medium has been advanced. However, since the operation has been initiated at the device, the device presents channel-end status, causing the channel subsystem to recognize a primary interruption condition. Subsequently, the device also presents device-end status, causing the channel subsystem to recognize a secondary interruption condition. Whether a block at the device is advanced when no data is transferred depends on the type of device.

When command chaining takes place, the subchannel is in the subchannel-and-device-active state from the time the first I/O operation is initiated at the device until the device presents channel-end status for the last I/O operation of the chain. The subchannel remains in the device-active state until the device presents the device-end status for the last I/O operation of the chain.

Any unusual conditions cause command chaining to be suppressed and a primary interruption condition to be generated. The unusual conditions can be detected by either the channel subsystem or the device, and the device can provide the indications with channel end, control unit end, or device end. When the channel subsystem is aware of the unusual condition by the time the channel-end status for the operation is accepted, the chain is ended as if the operation during which the condition occurred were the last operation of the chain. The device-end status is recognized as a secondary interruption condition whether presented together with the channel-end status or separately. If the device presents unit check or unit exception together with either control unit end or device end as status that causes the channel subsystem to recognize the primary interruption condition, then the subchannel-and-device-active state of the subchannel is terminated, and the subchannel is made status pending with primary, secondary, and

alert status. Intermediate status may also be indicated if an intermediate interruption condition previously existed at the subchannel for the initial-status-interruption condition or the PCI condition and that condition still remains pending at the subchannel. The channel-end status that was presented to the channel subsystem previously when command chaining was signaled is not made available to the program.

---

## Channel-Path-Reset Function

Subsequent to the execution of RESET CHANNEL PATH, the channel-path-reset function is performed. The performance of the function consists of: (1) issuing the reset signal on the designated channel path and (2) causing a channel report to be made pending, indicating the completion of the channel-path-reset function.

### Channel-Path-Reset-Function Signaling

The channel subsystem issues the reset signal on the designated channel path. As part of this operation, the following actions are taken:

1. All internal indications associated with control-unit-busy, device-busy, and allegiance conditions for the designated channel path are reset. These indications are reset at all subchannels that have access to the designated channel path. The reset function has no other effect on subchannels, including those having I/O operations in progress.
2. If the channel path fails to respond properly to the reset signal (see "I/O-System Reset" on page 17-12 for a detailed description) or, because of a malfunction, the reset signal could not be issued, the channel path is made physically not available at each applicable subchannel.
3. If an I/O operation is in progress at the device and the device is actively communicating on the channel path in the performance of that I/O operation when the reset signal is received on that channel path, the I/O operation is reset, and the control unit and device immediately terminate current communication with the channel sub-

system. (To avoid possible misinterpretation of unsolicited device-end status, programming measures can be taken as described in programming note 2 on page 15-46.)

4. If an I/O operation is in progress in the multipath mode at the device and the device is not currently communicating over the channel path in the performance of that I/O operation when the reset signal is received, then the I/O operation may or may not be reset depending on whether another channel path is available for selection in the same multipath group for the device. If there is at least one other channel path in the multipath group for the device that is available for selection, the I/O operation is not reset. However, the channel path on which the system reset is received is removed from the current set of channel paths that form the multipath group. If the channel path on which the reset signal is received is the only channel path of a multipath group, or if the device is operating in the single-path mode, the I/O operation is reset.
5. The channel-path-reset function causes I/O operations to be terminated at the device as described above; however, I/O operations are *never* terminated at the subchannel by the channel-path-reset function.

If an I/O operation is in progress at the subchannel and the channel path designated for the performance of the channel-path-reset function is being used for that I/O operation, the subchannel may or may not accurately reflect the progress of the I/O operation up to that instant. The subchannel remains in the state that exists at the time the channel-path-reset function is performed until the state is changed because of some action taken by the program or by the device.

## Channel-Path-Reset-Function-Completion Signaling

After the reset signal has been issued and an attempt has been made to issue the reset signal, or after it has been determined that the reset signal cannot be issued, the channel-path-reset function is completed. (See "Reset Signal" on page 17-12.)

As a result of the channel-path-reset function being performed, a channel report is made pending (see "Channel-Subsystem Recovery" on page 17-24)

to report the results. If the channel path responds properly to the system-reset signal, the channel report indicates that the channel path has been initialized and is physically available for use. If the reset signal was issued but either the channel path failed to respond properly or the channel path was already not physically available at each subchannel having access to the channel path, the channel report indicates that the channel path has been initialized but is not physically available for use. If, because of a malfunction or because the designated channel path is not in the configuration, the reset signal could not be issued, the channel report indicates that the channel path has not been initialized and is not physically available for use.

### Programming Notes:

1. If an I/O operation is in progress in the multipath mode when the channel-path-reset function is performed on a channel path of the multipath group, it is possible for the I/O operation to be continued on a remaining channel path of the group.
2. When the performance of the channel-path-reset function causes the I/O operation at the device to be reset, unsolicited device-end status presented by the device, if any, may be erroneously interpreted by the channel subsystem to be chaining status and thus cause the channel subsystem to continue the chain of commands. If this situation occurs, then the device-end status is not made available to the program, and the device is selected again by the channel subsystem; however, the device may interpret the initiation sequence as the beginning of a new channel program instead of as command chaining. This possibility can be avoided by issuing CLEAR SUBCHANNEL or HALT SUBCHANNEL, designating the affected subchannels, prior to issuing RESET CHANNEL PATH.
3. The performance of the channel-path-reset function may, on some models, cause overruns to occur on other channel paths.
4. Even though reset is signaled on the designated channel path, by one or more devices may not have been reset because of a malfunction at a control unit or a malfunction at the physical channel path to the control unit.

Status Control (SC) .....	16-16		

When an I/O operation or sequence of I/O operations initiated by the execution of START SUBCHANNEL is ended, the channel subsystem and the device generate status conditions. The generation of these conditions can be brought to the attention of the program by means of an I/O interruption or by means of the execution of the TEST PENDING INTERRUPTION instruction. (During certain abnormal situations, these conditions can be brought to the attention of the program by means of a machine-check interruption. See "Channel-Subsystem Recovery" on page 17-24 for details.)

The status conditions, as well as an address and a count indicating the extent of the operation sequence, are presented to the program in the form of a subchannel-status word (SCSW). The SCSW is stored in an interruption-response block (IRB) during the execution of TEST SUBCHANNEL.

Normally an I/O operation is being performed until the device signals primary interruption status. Primary interruption status can be signaled during initia-

tion of an I/O operation, or later. An I/O operation can be terminated by the channel subsystem performing a clear or halt function when it detects an equipment malfunction, a program check, a chaining check, a protection check, or an incorrect-length condition, or by performing a clear, halt, or channel-path-reset function as a result of the execution of CLEAR SUBCHANNEL, HALT SUBCHANNEL, or RESET CHANNEL PATH, respectively.

I/O interruptions provide a means for the CPU to change its state in response to conditions that occur at I/O devices or subchannels. These conditions can be caused by the program, by the channel subsystem, or by an external event at the device.

## Interruption Conditions

The conditions causing requests for I/O interruptions to be initiated are called I/O-interruption conditions. When an interruption condition is recognized by the

channel subsystem, it is indicated at the appropriate subchannel. The subchannel is then said to be status pending. The subchannel becoming status pending causes the channel subsystem to generate an I/O-interruption request. An I/O-interruption request can be brought to the attention of the program only once.

An I/O-interruption request remains pending until it is accepted by a CPU in the configuration, is withdrawn by the channel subsystem, or is cleared by means of the execution of TEST PENDING INTERRUPTION, TEST SUBCHANNEL, or CLEAR SUBCHANNEL, or by means of subsystem reset. When a CPU accepts an interruption request and stores the associated interruption code, the interruption request is cleared. Alternatively, an I/O-interruption request can be cleared by means of the execution of TEST PENDING INTERRUPTION. In either case, the subchannel remains status pending until the associated interruption condition is cleared when TEST SUBCHANNEL or CLEAR SUBCHANNEL is executed or when the subchannel is reset.

An I/O-interruption condition is normally cleared by means of the execution of TEST SUBCHANNEL. If TEST SUBCHANNEL is executed, designating a subchannel that has an I/O-interruption request pending, both the interruption request and the interruption condition at the subchannel are cleared. The interruption request and the interruption condition can also be cleared by CLEAR SUBCHANNEL.

A device-end status condition generated by the I/O device and presented following the conclusion of the last I/O operation of a start function is reset at the subchannel by the channel subsystem without generating an I/O-interruption condition or I/O-interruption request if the subchannel is currently start pending and if the status contains device end either alone or accompanied by control unit end. If any other status bits accompany the device-end status bit, then the channel subsystem generates an I/O-interruption request with deferred condition code 1 indicated.

When an I/O operation is terminated because of an unusual condition detected by the channel subsystem during the command-initiation sequence, status describing the interruption condition is placed at the subchannel, causing it to become status pending. If the unusual condition is detected by the device, the device-status field of the associated SCSW identifies the condition.

When command chaining takes place, the generation of status by the device does not cause an interruption, and the status is not made available to the program.

When the channel subsystem detects any of the following interruption conditions, it initiates a request for an I/O interruption without necessarily communicating with, or having received the status byte from, the device:

- A programming error associated with the contents of the ORB passed to the subchannel by the previous execution of START SUBCHANNEL
- A suspend flag set to one in the first CCW fetched that initiates channel-program execution for either START SUBCHANNEL or RESUME SUBCHANNEL, and suppress suspended interruption not specified in the ORB
- A programming error associated with the first CCW or first IDAW or MIDAW.

These interruption conditions from the subchannel, except for the suspended condition, can be accompanied by other subchannel-status indications, but the device-status indications are all stored as zeros.

The channel subsystem issues the clear signal to the device when status containing unit check is presented to a subchannel that is disabled or when the device is not associated with any subchannel. However, if the presented status does not contain unit check, the status is accepted by the channel subsystem and discarded without causing the subchannel to become status pending.

An interruption condition caused by the device may be accompanied by multiple device-status conditions. Furthermore, more than one interruption condition associated with the same device can be accepted by the channel subsystem without an intervening I/O interruption. As an example, when the channel-end condition is not cleared at the device by the time device end is generated, both conditions may be cleared at the device concurrently and indicated in the SCSW together. Alternatively, channel-end status may have been previously accepted at the subchannel, and an I/O interruption may have occurred; however, the associated status-pending condition may not have been cleared by TEST SUBCHANNEL by the time device-end status was accepted at the subchannel. In this situation, the device-end status may

be merged with the channel-end status without causing an additional I/O interruption. Whether an interruption condition may be merged at the subchannel with other existing interruption conditions depends upon whether the interruption condition is unsolicited or solicited.

**Unsolicited Interruption Condition:** An unsolicited interruption condition is any interruption condition that is unrelated to the performance of a clear, halt, resume, or start function. An unsolicited interruption condition is identified at the subchannel as alert status. An unsolicited interruption condition can be generated only when the subchannel is not device active.

The subchannel and device status associated with an unsolicited interruption condition is never merged with that of any currently existing interruption condition. If the subchannel is currently status pending, the unsolicited interruption condition is held in abeyance

in either the channel subsystem or the device, as appropriate, until the status-pending condition has been cleared. Whenever the subchannel is idle and zero status is presented by the device, the status is discarded.

**Solicited Interruption Condition:** A solicited interruption condition is any interruption condition generated as a direct consequence of performing or attempting to perform a clear, halt, resume, or start function. Solicited interruption conditions include any interruption condition generated while the subchannel is either subchannel-and-device active or device active. The subchannel and device status associated with a solicited interruption condition may be merged at the subchannel with that of another currently existing solicited interruption condition. Figure 16-1 on page 16-3 describes the interruption condition that results from any combination of bits in the status-control field of the SCSW.

Status-Control Field	Status-Control-Bit Combinations																	
	Alert	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0
Primary	0	1	1	1	1	0	0	1	1	1	1	0	0	0	0	0	0	0
Secondary	0	0	1	1	0	1	1	0	0	1	1	0	1	1	0	0	0	0
Intermediate	0	0	0	1	1	0	1	0	0	1	1	0	1	1	1	1	0	0
Status pending	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
Resulting interruption condition	E	S	S	S	S	S	-	S	S	S	S	S	S	S	-	S	S	

**Explanation:**

- Combination does not occur.
- E Unsolicited or solicited interruption condition.
- S Solicited interruption condition.
- 0 Indicates the bit stored as zero.
- 1 Indicates the bit stored as one.

Figure 16-1. Interruption Condition for Status-Control-Bit Combinations

## Intermediate Interruption Condition

An intermediate interruption condition is a solicited interruption condition that indicates that an event has occurred for which the program had previously requested notification. An intermediate interruption condition is described by solicited subchannel status, the Z bit, the subchannel-suspended condition, or any combination of the three. An intermediate interruption condition can occur only after it has been requested by the program through the use of flags in the ORB or a CCW. Depending on the state of the subchannel, the performance or suspension of the

I/O operation continues, unaffected by the setting of the intermediate-status bit.

An intermediate interruption condition can be indicated only together with one of the following indications:

1. Subchannel active
2. Status pending with primary status alone
3. Status pending with primary status together with alert status or secondary status or both
4. Suspended

If only the intermediate-status bit and the status-pending bit of the status-control field are ones during the execution of TEST SUBCHANNEL, the device-status field is zero.

## Primary Interruption Condition

A primary interruption condition is a solicited interruption condition that indicates the performance of the start function is completed at the subchannel. A primary interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with primary status. Once the primary interruption condition is indicated at the subchannel, the channel subsystem is no longer actively participating in the I/O operation by transferring commands or data. When a subchannel is status pending with a primary interruption condition, the execution of any of the following instructions results in the setting of a nonzero condition code: HALT SUBCHANNEL, MODIFY SUBCHANNEL, RESUME SUBCHANNEL, and START SUBCHANNEL. Once the primary interruption condition is cleared by the execution of TEST SUBCHANNEL, the subchannel accepts the START SUBCHANNEL instruction. (See "START SUBCHANNEL" on page 14-15)

## Secondary Interruption Condition

A secondary interruption condition is a solicited interruption condition that normally indicates the completion of an I/O operation at the device. A secondary interruption condition is also generated by the channel subsystem if the start function is terminated because a solicited alert interruption condition is recognized prior to initiating the first I/O operation at the device. A secondary interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with secondary status. Once the channel subsystem has accepted status from the device that causes a secondary interruption condition to be recognized, the start function is completed at the device.

## Alert Interruption Condition

An alert interruption condition is either a solicited interruption condition that indicates the occurrence of an unusual condition in a halt, resume, or start func-

tion or an unsolicited interruption condition that describes a condition unrelated to the performance of a halt, resume, or start function. An alert interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with alert status. An alert interruption condition may be generated by either the channel subsystem or the device. Nonzero alert status is always brought to the attention of the program.

---

## Priority of Interruptions

All requests for an I/O interruption are asynchronous to any activity in any CPU, and interruption requests associated with more than one subchannel can exist at the same time. The priority of interruptions is controlled by two types of mechanisms — one establishes within the channel subsystem the priority among interruption requests from subchannels associated with the same I/O-interruption subclass, and another establishes within a given CPU the priority among requests from subchannels of different I/O-interruption subclasses. The channel subsystem requests an I/O interruption only after it has established priority among requests from its subchannels. The conditions responsible for the I/O-interruption requests associated with subchannels are preserved at the subchannels until cleared by a CPU's execution of TEST SUBCHANNEL or CLEAR SUBCHANNEL or I/O-system reset is performed.

The assignment of priority among requests for interruption from subchannels of the same I/O-interruption subclass is in the order that the need for interruption is recognized by the channel subsystem. The order of recognition by the channel subsystem is a function of the type of interruption condition and the type of channel path. For the parallel-I/O-interface type of channel path, the order depends on the electrical position of the device on the channel path to which it is attached. (A device's electrical position on the parallel-I/O interface is not related to its device address.)

The assignment of priority among requests for interruption from subchannels of different I/O-interruption subclasses is made by the CPU according to the numerical value of the I/O-interruption subclass codes (with zero having highest priority), in conjunction with the I/O-interruption-subclass mask in control register 6. The numerical value of the I/O-interrup-

tion-subclass code directly corresponds to the bit position in the I/O-interruption-subclass mask in control register 6 of a CPU. If, in any CPU, an I/O-interruption-subclass-mask bit is zero, then all subchannels having an I/O-interruption-subclass code numerically equal to the associated position in the mask register are said to be masked off in the respective CPU. Therefore, a CPU accepts the highest-priority I/O-interruption request from a subchannel that has the lowest-numbered I/O-interruption subclass code that is not masked off by a corresponding bit in control register 6 of that CPU. When the highest-priority interruption request is accepted by a CPU, it is cleared so that the interruption request is not accepted by any other CPU in the configuration.

The priority of interruption handling can be modified by the execution of either TEST SUBCHANNEL or CLEAR SUBCHANNEL. When either of these instructions is executed and the designated subchannel has an interruption request pending, that interruption request is cleared, without regard to any previous established priority. The relative priority of the remaining interruption requests is unchanged.

#### **Programming Notes:**

1. The I/O-interruption subclass mask is in control register 6, which has the following format:

##### **Word**

0																
0																31
1																
32																40

2. Control register 6 is set to all zeros during initial CPU reset.

---

## **Interruption Action**

An I/O interruption can occur only when the I/O-interruption-subclass-mask bit associated with the subchannel is one and the CPU is enabled for I/O interruptions.

The interruption occurs at the completion of a unit of operation (see "Point of Interruption" on page 5-20).

If the channel subsystem establishes the priority among requests for interruption from subchannels while the CPU is disabled for I/O interruptions, the interruption occurs immediately after the completion of the instruction enabling the CPU and before the next instruction is executed, provided that the I/O-interruption subclass-mask bit associated with the subchannel is one. Alternatively, if the channel subsystem establishes the priority among requests for interruption from subchannels while the I/O-interruption-subclass-mask bit is zero for each subchannel that is status pending, the interruption occurs immediately after the completion of the instruction that sets at least one of the I/O-interruption-subclass-mask bits to one, provided that the CPU is also enabled for I/O interruptions. This interruption is associated with the highest-priority I/O-interruption request, as established by the CPU.

If the channel subsystem has not established the priority among requests for interruption from the subchannels by the time the interruption is allowed, the interruption does not necessarily occur immediately after the completion of the instruction enabling the CPU. A delay can occur regardless of how long the interruption condition has existed at the subchannel.

The interruption causes the current PSW to be stored as the input/output old PSW at real locations 368-383 and causes the I/O-interruption code associated with the interruption to be stored at real locations 184-195 of the CPU allowing the interruption. Subsequently, a new input/output PSW is loaded from real locations 496-511 and processing resumes in the CPU state indicated by that PSW. The subchannel causing the interruption is identified by the interruption code.

The I/O-interruption code has the following format when it is stored. The code is described in "TEST PENDING INTERRUPTION" on page 14-19.

##### **Hex.**

B8	184	Subsystem-Identification Word
BC	188	I/O-Interruption Parameter
C0	192	I/O-Interruption-Identification Word

**Programming Note:** The I/O-interruption subclass code for all subchannels is set to zero by I/O-system

reset. It may be set to any of the values 0-7 by the execution of MODIFY SUBCHANNEL. (The operation of the instruction is described in “MODIFY SUBCHANNEL” on page 14-7.)

## Interruption-Response Block

The interruption-response block (IRB) is the operand of TEST SUBCHANNEL. The two rightmost bits of the IRB address are zeros, designating the IRB on a word boundary. The IRB contains three major fields: the subchannel-status word, the extended-status word, and the extended-control word. When the extended-I/O-measurement-word mode is enabled at the subchannel, the IRB contains a fourth major field, the extended-measurement word. The format of the IRB is as follows:

Word	
0	
1	Subchannel-Status Word
2	
3	
:	Extended-Status Word
7	
8	
15	Extended-Control Word
16	
:	Extended-Measurement Word
23	

The length of the subchannel-status and extended-status words is 12 bytes and 20 bytes, respectively. The length of the extended-control word is 32 bytes. When the extended-control bit, bit 14 of word 0 of the SCSW, is zero, words 8-15 of the interruption-response block may or may not be stored. The length of the extended-measurement word is 32 bytes. When the conditions for storing the extended-measurement word are not met (see “Extended-Measurement Word” on page 16-42), words 16-23 of the interruption-response block may or may not be stored.

## Subchannel-Status Word

The subchannel-status word (SCSW) provides to the program indications describing the status of a subchannel and its associated device. If performance of a halt, resume, or start function has occurred, the SCSW may describe the conditions under which the operation was concluded.

The SCSW is stored when TEST SUBCHANNEL is executed and the designated subchannel is operational. The SCSW is placed in words 0-2 of the IRB that is designated as the TEST SUBCHANNEL operand. When STORE SUBCHANNEL is executed, the SCSW is stored in words 7-9 of the subchannel-information block (described in “Subchannel-Information Block” on page 15-1).

Figure 16-2 on page 16-7 shows the format of the SCSW and summarizes its contents.

**Word**

0	Key	S	L	CC	F	P	I	A	U	Z	E	N	0	FC	AC	SC

16-31	Count

*Figure 16-2. SCSW Format*

The contents of the subchannel-status word (SCSW) depend on the state of the subchannel when the SCSW is stored. Depending on the state of the subchannel and the device, the specific fields of the SCSW may contain (1) information pertaining to the last operation, (2) information unrelated to the performance of an operation, (3) zeros, or (4) meaningless values. The following descriptions indicate when an SCSW field contains meaningful information.

**Subchannel Key**

When the start-function bit, bit 17 of word 0, is one, bit positions 0-3 of word 0 contain the access key used during performance of the associated start function. These bits are identical with the key specified in bit positions 0-3 of word 1 of the ORB. The subchannel key is meaningful only when the start-function bit, bit 17 of word 0, is one.

## Suspend Control (S)

When the start-function bit, bit 17 of word 0, is one, bit 4 of word 0, when one, indicates that the suspend function can be initiated at the subchannel. Bit 4 is meaningful only when bit 17 is one. If bit 17 is one and bit 4 is one, channel-program execution can be suspended if the channel subsystem recognizes an S flag set to one in a CCW. If bit 4 is zero, channel-program execution cannot be suspended, and, if an S flag set to one in a CCW is encountered, a program-check condition is recognized.

## Extended-Status-Word Format (L)

When the status-pending bit, bit 31 of word 0, is one, bit 5 of word 0, when one, indicates that a format-0 ESW has been stored. A format-0 ESW is stored when an interruption condition containing any of the following indications is cleared by TEST SUBCHANNEL:

- Channel-data check
- Channel-control check
- Interface-control check
- Measurement-block-program check
- Measurement-block-data check
- Measurement-block-protection check
- Path verification required
- Authorization check
- Extended subchannel logout pending

The extended-status-word-format bit is meaningful whenever the subchannel is status pending. The extended-status information that is used to form a format-0 ESW is cleared at the subchannel by TEST SUBCHANNEL or CLEAR SUBCHANNEL.

## Deferred Condition Code (CC)

When the start-function bit, bit 17 of word 0, is one and the status-pending bit, bit 31 of word 0, is also one, bits 6 and 7 of word 0 indicate the general reason that the subchannel was status pending when TEST SUBCHANNEL or STORE SUBCHANNEL was executed. The deferred condition code is meaningful when the subchannel is status pending with any combination of status and only when the start-function bit of the function-control field in the SCSW is one. The meaning of the deferred condition code for each value when the subchannel is status pending is given in Figure 16-3 on page 16-10.

The deferred condition code, if not zero, is used to indicate whether conditions have been encountered that preclude the subchannel becoming subchannel-

and-device active while the subchannel is either start pending or suspended.

**Deferred Condition Code 0:** A normal I/O interruption has taken place.

**Deferred Condition Code 1:** Status is present in the SCSW that was presented by the associated device or generated by the channel subsystem subsequent to the setting of condition code 0 for START SUBCHANNEL or RESUME SUBCHANNEL. If only the alert-status bit and the status-pending bit of the status-control field of the SCSW are ones, the status present is not related to the execution of a channel program. If the intermediate-status bit, the primary-status bit, or both are ones, then the status is related to the execution of the channel program specified by the most recently executed START SUBCHANNEL instruction or implied by the most recently executed RESUME SUBCHANNEL instruction. (See “Immediate Conclusion of I/O Operations” on page 15-43.) If the secondary-status bit is one and the primary-status bit is zero, the status present is related to the channel program specified by the START SUBCHANNEL instruction or implied by the RESUME SUBCHANNEL instruction that preceded the most recently executed START SUBCHANNEL instruction.

**Deferred Condition Code 2:** This code does not occur and is reserved for future use.

**Deferred Condition Code 3:** An attempted device selection has occurred, and the device appeared not operational on all of the channel paths that were available for selection of the device.

A device appears not operational when it does not respond to a selection attempt by the channel subsystem. This occurs when the control unit is not provided in the system, when power is off in the control unit, or when the control unit has been logically switched off the channel path. The not-operational state is also indicated when the control unit is provided and is capable of attaching the device, but the device has not been installed and the control unit is not designed to recognize the device being selected as one of its attached devices. (See also “I/O Addressing” on page 13-5.)

A deferred condition code 3 also can be set by the channel subsystem if no channel paths to the device are available for selection. (See Figure 16-3 on page 16-10.)

**Programming Notes:**

1. If, during performance of a start function, the I/O device being selected is not installed or has been logically removed from the control unit, but the associated control unit is operational and the control unit recognizes the I/O device being selected as one of its I/O devices, the control unit, depending upon the model, either fails to recognize the address of the I/O device or considers the I/O device to be not ready. In the former case, a path-not-operational condition is recognized, subject to the setting of the path-operational mask. (See “Path-Operational Mask (POM)” on page 15-6.) In the latter case, the not-ready condition is indicated when the control unit responds to the selection and indicates unit check whenever the not-ready state precludes successful initiation of the operation at the I/O device. In this case, unit-check status is indicated in the SCSW, the subchannel becomes status pending with primary, secondary, and alert status, and with deferred condition code 1 indicated. (See the publication *ESA/390 Common I/O-Device Commands*, SA22-7204, for a description of unit-check status.) Refer to the System Library publication for the control unit to determine how the condition is indicated.
2. The deferred condition code is 1, and the status-control field contains the status-pending and intermediate-status bits or the status-pending, intermediate-status, and alert-status bits as ones when HALT SUBCHANNEL has been executed and the designated subchannel is suspended and status pending with intermediate status. If the alert-status bit is one, then subchannel-logout information was generated as a result of attempting to issue the halt signal to the device.

Bit 6	Bit 7	Status Control <sup>1</sup>	Meaning
0	0	A I P S X	Normal I/O Interruption
		A I P - X	
		A - P S X	
		A - P - X	
		- I P S X	
		- I P - X	
		- I - - X	
		- - P S X	
		- - P - X	
0	1	A I P S X	Either an immediate operation, with chaining not specified, has ended normally, or the setting of some status condition precluded the initiation or resumption of a requested I/O operation at the device.
		A I P - X	
		A I - - X <sup>2</sup>	
		A - P S X	
		A - P - X	
		A - - S X	
		A - - - X	
		- I P S X	
		- I P - X	
		- I - - X <sup>2</sup>	
		- - P S X	
		- - P - X	
		- - - S X <sup>3</sup>	
		- - - - X <sup>3</sup> <sup>2</sup>	
1	0	Reserved	Reserved
1	1	- - P S X - I P S X	The device is not operational on any available path or, if a dedicate-allegiance condition exists, the device is not operational on the path to which the dedicated-allegiance is owed.

**Explanation:**

- Bit is zero.

<sup>1</sup> The allowed combinations of status-control-bit settings when the start-function bit is one in the function-control field.

<sup>2</sup> The condition is encountered after the execution of HALT SUBCHANNEL when the subchannel is currently suspended.

<sup>3</sup> The condition is encountered after the execution of HALT SUBCHANNEL when the subchannel is currently start pending.

A Alert status.  
I Intermediate status.  
P Primary status.  
S Secondary status.  
X Status pending.

Figure 16-3. Deferred-Condition-Code Meaning for Status-Pending Subchannel

## Format (F)

When the start-function bit, bit 17 of word 0, is one, bit 8 of word 0 indicates the format of the CCWs associated with an I/O operation. The format bit is meaningful only when bit 17 is one. If bit 8 of word 0 is zero, format-0 CCWs are indicated. If it is one, format-1 CCWs are indicated. (See “Channel-Com-

mand Word” on page 15-26 for the description of the two CCW formats.)

## Prefetch (P)

When the start-function bit, bit 17 of word 0, is one, bit 9 of word 0 indicates whether or not unlimited prefetching of CCWs, IDAWS, MIDAWS, and associ-

ated data is allowed. The prefetch bit is meaningful only when bit 17 is one. If bit 9 is zero, prefetching of one CCW describing a data area is allowed during output-data-chaining operations and is not allowed during any other operations. If bit 9 is one, unlimited prefetching of CCWs, IDAWs, MIDAWS, and associated data is allowed. It is model dependent whether prefetching is actually performed for any or all of the CCWs, IDAWs, MIDAWS, and associated data that comprise the channel program.

### **Initial-Status-Interruption Control (I)**

When the start-function bit, bit 17 of word 0, is one, bit 10 of word 0, when one, indicates that the channel subsystem is to generate an intermediate interruption condition if the subchannel becomes subchannel active (see “Initial-Status-Interruption Control (I)” on page 15-23). Bit 10 of word 0, when zero, indicates that the subchannel becoming subchannel active is not to cause an intermediate interruption condition to be generated.

The program requests the intermediate interruption condition by means of the ORB. An I/O interruption that results from that request may be due to the channel subsystem performing either a start function or a resume function. (See “Zero Condition Code (Z)” on page 16-11 for details of the indication given by the channel subsystem when the intermediate interruption condition is cleared by TEST SUBCHANNEL.)

### **Address-Limit-Checking Control (A)**

When the start-function bit, bit 17 of word 0, is one, bit 11 of word 0, when one, indicates that the channel subsystem has been requested by the program to perform address-limit checking, subject to the setting of the limit mode at the subchannel (see “Address-Limit-Checking Control (A)” on page 15-24). The address-limit-checking-control bit is meaningful only when bit 17 is one.

### **SUPPRESS-SUSPENDED INTERRUPTION (U)**

When the start-function bit, bit 17 of word 0, is one, bit 12 of word 0, when one, indicates that the channel subsystem has been requested by the program to suppress the generation of a subchannel-suspended interruption condition when the subchannel is suspended (see “SUPPRESS-SUSPENDED-INTERRUPTION CONTROL (U)” on page 15-24). When bit 12 is zero, the channel subsystem generates an intermediate interruption condition whenever the subchannel is suspended during the execution of the associated

channel program. The suppress-suspended-interruption bit is meaningful only when bit 17 is one.

## **Subchannel-Control Field**

The following subchannel-control-information descriptions apply to the subchannel-control field, bits 13-31 of word 0 of the SCSW.

### **Zero Condition Code (Z)**

Bit 13 of word 0, when one, indicates that the subchannel has become subchannel active and the channel subsystem has recognized an initial-status-interruption condition at the subchannel. The Z bit is meaningful only when the intermediate-status bit, bit 28 of word 0, and the start-function bit, bit 17 of word 0, are both ones.

If the initial-status-interruption-control bit, bit 10 of word 1 of the ORB, is one when START SUBCHANNEL is executed, then the subchannel becoming subchannel active causes the subchannel to be made status pending with intermediate status indicating the initial-status-interruption condition. The initial-status-interruption condition remains at the subchannel until the intermediate interruption condition is cleared by the execution of TEST SUBCHANNEL or CLEAR SUBCHANNEL. If the initial-status-interruption-control bit of the ORB is zero when START SUBCHANNEL is executed, then the subchannel becoming subchannel active does not cause an intermediate interruption condition to be generated, and the initial-status-interruption condition is not recognized.

### **Extended Control (E)**

Bit 14 of word 0, when one, indicates that model-dependent information or concurrent-sense information is stored in the extended-control word (ECW). When bit 14 is zero, the contents of words 0-7 of the ECW, if stored, are unpredictable. The E bit is meaningful whenever the subchannel is status pending with alert status either alone or together with primary status, secondary status, or both.

**Programming Note:** During the execution of TEST SUBCHANNEL, the storing of words 0-7 of the ECW is a model-dependent function subject to the setting of bit 14 as described above. Therefore, the program should always provide sufficient storage to accommodate the storing of a 64-byte IRB.

## **Path Not Operational (N)**

Bit 15 of word 0, when one, indicates that the N condition has been recognized by the channel subsystem. The N condition, in turn, indicates that one or more path-not-operational conditions have been recognized. The channel subsystem recognizes a path-not-operational condition when, during an attempted device selection in order to perform a clear, halt, resume, or start function, the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel. A channel path is operational for the subchannel if the associated device appeared operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A channel path is not operational for the subchannel if the associated device appeared not operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A device appears to be operational on a channel path when the device responds to an attempted device selection.

The N bit is meaningful whenever the status-control field contains any of the indications listed below and at least one basic I/O function is also indicated at the subchannel:

- Status pending with any combination of primary, secondary, or alert status
- Status pending alone
- Status pending with intermediate status when the subchannel is also suspended

The N condition is reset whenever the execution of TEST SUBCHANNEL results in the setting of condition code 0 and the N bit is meaningful as described above.

### **Notes:**

1. A path-not-operational condition does not imply a malfunctioning channel path. A malfunctioning channel path causes the generation of an error indication, such as interface-control check.
2. When a path-not-operational condition has been recognized and the subchannel subsequently becomes status pending with only intermediate status, the path-not-operational condition (a) continues to be recognized until the subchannel becomes status pending with primary status

or becomes suspended and (b) is indicated by storing the path-not-operational bit as a one during the execution of TEST SUBCHANNEL. When a path-not-operational condition has been recognized and the channel-program execution subsequently becomes suspended, the path-not-operational condition does not remain pending if channel-program execution is subsequently resumed. Instead, the old indication is lost, and the path-not-operational indication, if any, pertains to the attempt by the channel subsystem to resume channel-program execution.

## **Function Control (FC)**

The function-control field indicates the basic I/O functions that are indicated at the subchannel. This field may indicate the acceptance of as many as two functions. The function-control field is contained in bit positions 17-19 of the first word of the SCSW. The function-control field is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 15-4). The function-control field contains all zeros whenever both the activity- and status-control fields contain all zeros. The meaning of the individual bits is as follows:

***Start Function (Bit 17):*** When one, bit 17 indicates that a start function has been requested and is either pending or in progress at the subchannel. A start function is requested by the execution of START SUBCHANNEL. A start function is indicated at the subchannel when condition code 0 is set during the execution of START SUBCHANNEL. The start-function indication is cleared at the subchannel when TEST SUBCHANNEL is executed and the subchannel is either status pending alone or status pending with any combination of alert, primary, or secondary status. The start-function indication is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

***Halt Function (Bit 18):*** When one, bit 18 indicates that a halt function has been requested and is either pending or in progress at the subchannel. A halt function is requested by the execution of HALT SUBCHANNEL. A halt function is indicated at the subchannel when condition code 0 is set for HALT SUBCHANNEL. The halt-function indication is cleared at the subchannel when the next status-pending condition that occurs is cleared by the execution of TEST SUBCHANNEL. The next status-pending condition depends on the state of the subchannel when HALT SUBCHANNEL is executed. If

the subchannel is subchannel active when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with at least primary status indicated. If the subchannel is device active when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with at least secondary status indicated. If the subchannel is suspended and status pending with intermediate status when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with intermediate status. If the subchannel is idle when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending alone. The halt-function indication is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL. In normal operations, this function is indicated together with bit 17; that is, there is a start function either pending or in progress that is to be halted.

**Clear Function (Bit 19):** When one, bit 19 indicates that a clear function has been requested and is either pending or in progress at the subchannel. A clear function is requested by the execution of CLEAR SUBCHANNEL. A clear function is indicated at the subchannel when condition code 0 is set for CLEAR SUBCHANNEL (see “CLEAR SUBCHANNEL” on page 14-5). The clear-function indication is cleared at the subchannel when the resulting status-pending condition is cleared by TEST SUBCHANNEL.

## Activity Control (AC)

The activity-control field is contained in bit positions 20-26 of the first word of the SCSW. This field indicates the current progress of a basic I/O function previously accepted at the subchannel. By using the contents of this field, the program can determine the degree of completion of the basic I/O function. The activity-control field is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 15-4). However, if an IFCC or CCC condition is detected during the performance of a basic I/O function and that function is indicated as pending, I/O operations may or may not

have been performed at the device. The activity-control bits are defined as follows:

Bit	Meaning
20	Resume pending
21	Start pending
22	Halt pending
23	Clear pending
24	Subchannel active
25	Device active
26	Suspended

When an SCSW is stored that has the status-pending bit of the status-control field zero and all zeros in the activity-control field, the subchannel is said to be idle or in the idle state.

**Note:** All conditions that are represented by the bits in the function-control field and by the resume-pending, start-pending, halt-pending, clear-pending, subchannel-active, and suspended bits in the activity-control field are reset at the subchannel when TEST SUBCHANNEL is executed and the subchannel is (1) status pending alone, (2) status pending with primary status, (3) status pending with alert status, or (4) status pending with intermediate status and is also suspended.

**Resume-Pending (Bit 20):** When one, bit 20 indicates that the subchannel is resume pending. The channel subsystem may or may not be in the process of performing the start function. The subchannel becomes resume pending when condition code 0 is set for RESUME SUBCHANNEL. The point at which the subchannel is no longer resume pending is a function of the subchannel state existing when the resume-pending condition is recognized and the state of the device if channel-program execution is resumed.

If the subchannel is in the suspended state when the resume-pending condition is recognized, the CCW that caused the suspension is refetched, the setting of the suspend flag is examined, and one of the following actions is taken by the channel subsystem:

1. If the CCW suspend flag is one, the device is not selected, the subchannel is no longer resume pending, and the channel-program execution remains suspended.
2. If the CCW suspend flag is zero, the channel subsystem attempts to resume channel-program execution by performing a modified start func-

tion. The resumption of channel-program execution appears to the device as the initiation of a new channel-program execution. The resume function causes the channel subsystem to perform the path-management operation as if a new start function were being initiated, using the ORB parameters previously passed to the subchannel by START SUBCHANNEL with the exception that the channel-program address is the address of the CCW that caused the suspension of the channel-program execution.

The subchannel remains resume pending when, during the performance of the start function, the channel subsystem (1) determines that it is not possible to attempt to initiate the I/O operation for the first command, (2) determines that an attempt to initiate the I/O operation for the first command does not result in the command being accepted, or (3) detects an IFCC or CCC condition and is unable to determine whether the first command has been accepted. (See "Start Function and Resume Function" on page 15-18.)

The subchannel is no longer resume pending when any of the following events occurs:

- a. While performing the start function, the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted with channel-end and device-end initial status and the CCW does not specify command chaining.
- b. CLEAR SUBCHANNEL is executed.
- c. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.
- d. TEST SUBCHANNEL clears intermediate status while the subchannel is suspended.
- e. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

If the subchannel is not in the suspended state when the resume-pending condition is recognized, the CCW suspend flag of the most recently fetched CCW, if any, is examined, and one of the following actions is taken by the channel subsystem:

1. If a CCW has not been fetched or the suspend flag of the most recently fetched CCW is zero, the subchannel is no longer resume pending, and the resume function is not performed.

2. If the suspend flag of the most recently fetched CCW is one, the subchannel is no longer resume pending, and the CCW is refetched. The subchannel proceeds with channel-program execution if the suspend flag of the refetched CCW is zero. The subchannel suspends channel-program execution if the suspend flag of the refetched CCW is one.

Some models recognize a resume-pending condition only after a CCW having an S flag validly set to one is fetched. Therefore, if a subchannel is resume pending and, during the execution of the channel program, no CCW is fetched that has an S flag validly set to one, the subchannel remains resume pending until the primary interruption condition is cleared by TEST SUBCHANNEL.

**Start-Pending (Bit 21):** When one, bit 21 indicates that the subchannel is start pending. The channel subsystem may or may not be in the process of performing the start function. The subchannel becomes start pending when condition code 0 is set for START SUBCHANNEL. The subchannel remains start pending when, during the performance of the start function, the channel subsystem (1) determines that it is not possible to attempt to initiate the I/O operation for the first command, (2) determines that an attempt to initiate the I/O operation for the first command does not result in the command being accepted, or (3) detects an IFCC or CCC condition and is unable to determine whether the first command has been accepted. (See "Start Function and Resume Function" on page 15-18.)

The subchannel becomes no longer start pending when any of the following occurs:

1. While performing the start function, the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted with channel-end and device-end initial status and the CCW does not specify command chaining.
2. The subchannel becomes suspended because of a suspend flag validly set to one in the first CCW.
3. CLEAR SUBCHANNEL is executed.
4. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.

- CANCEL SUBCHANNEL is executed with a resulting condition code 0.

**Halt-Pending (Bit 22):** When one, bit 22 indicates that the subchannel is halt pending. The channel subsystem may or may not be in the process of performing the halt function. The subchannel becomes halt pending when condition code 0 is set for HALT SUBCHANNEL. The subchannel remains halt pending when, during the performance of the halt function, the channel subsystem (1) determines that it is not possible to attempt to issue the halt signal to the device, (2) determines that the attempt to issue the halt signal to the device is not successful, or (3) detects an IFCC or CCC condition and is unable to determine whether the halt signal is issued to the device. (See “Halt Function” on page 15-15.)

The subchannel is no longer halt pending when any of the following occurs:

- While performing the halt function, the channel subsystem determines that the halt signal has been issued to the device.
- CLEAR SUBCHANNEL is executed.
- TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.
- TEST SUBCHANNEL clears intermediate status while the subchannel is suspended.

**Clear-Pending (Bit 23):** When one, bit 23 indicates that the subchannel is clear pending. The channel subsystem may or may not be in the process of performing the clear function. The subchannel becomes clear pending when condition code 0 is set for CLEAR SUBCHANNEL. The subchannel remains clear pending when, during performance of the clear function, the channel subsystem (1) determines that it is not possible to attempt to issue the clear signal to the device, (2) determines that the attempt to issue the clear signal to the device is not successful, or (3) detects an IFCC or CCC condition and is unable to determine whether the clear signal is issued to the device. (See “Clear Function” on page 15-13.)

The subchannel is no longer clear pending when either of the following occurs:

- While performing the clear function, the channel subsystem determines that the clear signal has been issued to the device.

- TEST SUBCHANNEL clears the status-pending condition alone.

**Subchannel Active (Bit 24):** When one, bit 24 indicates that the subchannel is subchannel active. A subchannel is said to be subchannel active when an I/O operation is currently being performed at the subchannel. The subchannel becomes subchannel active when the first command is accepted and the start function or resume function is not immediately concluded at the subchannel. (See “Immediate Conclusion of I/O Operations” on page 15-43.)

The subchannel is no longer subchannel active when any of the following occurs:

- The subchannel becomes suspended.
- The subchannel becomes status pending with primary status.
- CLEAR SUBCHANNEL is executed.
- The device appears not operational during performance of a halt function.

The subchannel does not become subchannel active during performance of the function specified by either a HALT SUBCHANNEL or a CLEAR SUBCHANNEL instruction.

**Device Active (Bit 25):** When one, bit 25 indicates that the subchannel is device active. A subchannel is said to be device active when an I/O operation is currently in progress at the associated device. The subchannel becomes device active when the first command is accepted.

The subchannel is no longer device active when any of the following occurs:

- The subchannel becomes suspended.
- The subchannel becomes status pending with secondary status.
- CLEAR SUBCHANNEL is executed.
- The device appears not operational during performance of a halt function.

If the subchannel is not start pending or if the status accepted from the device also describes an alert condition, the subchannel becomes status pending with secondary status. After the status has been accepted from the device, the device is capable of

accepting a command for performing a new I/O operation. If the subchannel is start pending and the status is device end or device end with control unit end, then the channel subsystem discards the status and performs the start function for the new channel program. (See “Start Function and Resume Function” on page 15-18) In this situation, the subchannel does not become status pending with the secondary interruption condition, and the status is not made available to the program.

The subchannel does not become device active during performance of the functions specified by either a HALT SUBCHANNEL or a CLEAR SUBCHANNEL instruction.

**Suspended (Bit 26):** When one, bit 26 indicates that the subchannel is suspended. A subchannel is said to be suspended when channel-program execution is currently suspended. The subchannel becomes suspended as part of the suspend function. (See “Suspension of Channel-Program Execution” on page 15-39.)

The subchannel is no longer suspended when any of the following occurs:

1. As part of the resume function following the execution of RESUME SUBCHANNEL when the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted for channel-end and device-end initial status, with or without status modifier, and the CCW does not specify command chaining.
2. CLEAR SUBCHANNEL is executed.
3. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.
4. TEST SUBCHANNEL clears intermediate status while the halt function is specified.
5. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

**Programming Note:** When an SCSW is stored by STORE SUBCHANNEL or TEST SUBCHANNEL following CLEAR SUBCHANNEL but prior to the subchannel becoming status pending, and the subchannel-active bit, bit 24 of word 0, is stored as zero, this does not mean that data transfer has stopped for the device. The program cannot determine whether data transfer has stopped until the sub-

channel becomes status pending as a result of performing the clear function.

## Status Control (SC)

The status-control field is contained in bit positions 27-31 of the first word of the SCSW. This field provides the program with a summary-level indication of the interruption condition described by either subchannel or device status, the Z bit, or, in the case of the subchannel-suspended interruption, the suspended bit, bit 26. More than one summary indication may be signaled as a result of existing conditions at the subchannel. Whenever the subchannel is enabled (see “Enabled (E)” on page 15-2) and at least bit 31 is one, the subchannel is said to be status pending. Whenever the subchannel is disabled, the subchannel is not made status pending. Bit 31 of SCSW word 0 is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 15-4); bits 27-30 are meaningful when bit 31 is one. The status-control bits are defined as follows:

**Alert Status (Bit 27):** When one (and when the status-pending bit is also one), bit 27 indicates an alert interruption condition exists. In such a case, the subchannel is said to be status pending with alert status. An alert interruption condition is recognized when alert status is present at the subchannel. Alert status may be subchannel status or device status. Alert status is status generated by either the channel subsystem or the device under any of the following conditions:

- The subchannel is idle (activity-control bits 20-26 and status-control bit 31 are zeros).
- The subchannel is start pending, and the status condition precludes initiation of the I/O operation.
- The subchannel is subchannel-and-device active, and the status condition has suppressed command chaining or would have suppressed command chaining if chaining had been specified (see “Chaining” on page 15-30).
- The subchannel is subchannel-and-device active, command chaining is not specified, the execution of the channel program has just been concluded, and the status presented by the device is attempting to alter the sequential execution of commands (see the publication *ESA/390 Common I/O-Device Commands*, SA22-7204, for more information on the use of

status modifier to alter the sequential execution of commands).

- The subchannel is device active only, and the status presented by the device is other than device end, control unit end, or device end and control unit end.
- The subchannel is suspended (bit 26 is one).

If the subchannel is start pending when an alert interruption condition is recognized, the subchannel becomes status pending with alert status, deferred condition code 1 is set, the start-pending bit remains one, and the performance of the pending I/O operation is not initiated.

When TEST SUBCHANNEL is executed and stores an SCSW with the alert-status bit and the status-pending bit as ones in the IRB, the alert interruption condition is cleared at the subchannel. The alert interruption condition is also cleared during the execution of CLEAR SUBCHANNEL.

Whenever alert status is present at the subchannel, it is brought to the attention of the program. Examples of alert status include attention, device end (which signals a transition from the not-ready to the ready state), incorrect length, program check, and unit check.

**Intermediate Status (Bit 28):** When one (and when the status-pending bit is also one), bit 28 indicates an intermediate interruption condition exists. In such a case, the subchannel is said to be status pending with intermediate status. Intermediate status can be indicated when the Z bit (of the subchannel-control field), the suspended bit (of the activity-control field), or the PCI bit (of the subchannel-status field) is one.

When the initial-status-interruption-control bit is one in the ORB, the subchannel becomes status pending with intermediate status (the Z bit indicated) only after the subchannel is subchannel active. If the subchannel does not become subchannel active, the Z condition is not generated.

When suspend control is specified and the generation of an intermediate interruption condition due to suspension is not suppressed in the ORB, then the subchannel can become status pending with intermediate status due to suspension if a CCW becomes current that contains the suspend flag set to one.

When the suspend flag is specified in the first CCW of a channel program, channel-program execution is suspended, and the subchannel becomes status pending with intermediate status (the suspended bit indicated) before the command in the first CCW is transferred to the device. When the suspend flag is specified in a CCW fetched during command chaining, then channel-program execution is suspended, and the subchannel becomes status pending with intermediate status (the suspended bit is indicated), only after the execution of the preceding CCW is complete.

When the PCI flag is specified in a CCW, the generation of an intermediate interruption condition due to PCI depends on whether the CCW is the first CCW of the channel program. When the PCI flag is specified in the first CCW of a channel program, the subchannel becomes status pending with intermediate status (the PCI bit indicated) only after initial status is received for the first CCW of the channel program indicating the command has been accepted. When the PCI flag is specified in a CCW fetched while chaining, the subchannel becomes status pending with intermediate status (the PCI bit indicated) only after the execution of the preceding CCW is complete. If chaining occurs before an interruption condition containing PCI is cleared by TEST SUBCHANNEL, the condition is carried over to the next CCW. This carry-over occurs during both data and command chaining, and, in either case, the condition is propagated through the transfer-in-channel command.

If the subchannel is status pending with intermediate status when HALT SUBCHANNEL is executed, the intermediate interruption condition remains at the subchannel, but the interruption request, if any, is withdrawn, and the subchannel becomes no longer status-pending. The subchannel remains no longer status pending until performance of the halt function has ended. The subchannel then becomes status pending with intermediate status indicated (possibly together with any combination of primary, secondary, and alert status).

When TEST SUBCHANNEL is executed and stores an SCSW with the intermediate-status bit and the status-pending bit as ones in the IRB, the intermediate interruption condition is cleared at the subchannel. The intermediate interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

**Primary Status (Bit 29):** When one (and when the status-pending bit is also one), bit 29 indicates a primary interruption condition exists. In such a case, the subchannel is said to be status pending with primary status. A primary interruption condition is a solicited interruption condition that indicates the completion of the start function at the subchannel. The primary interruption condition is described by the SCSW stored. When an I/O operation is terminated by HALT SUBCHANNEL but the halt signal is not issued to the device because the device appeared not operational, the subchannel is made status pending with primary status (and secondary status) with both the subchannel-status field and the device-status field set to zero.

When TEST SUBCHANNEL is executed and stores an SCSW with the primary-status bit and the status-pending bit as ones in the IRB, the primary interruption condition is cleared at the subchannel. The primary interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

**Secondary Status (Bit 30):** When one (and when the status-pending bit is also one), bit 30 indicates a secondary interruption condition exists. In such a case, the subchannel is said to be status pending with secondary status. A secondary interruption condition is a solicited interruption condition that normally indicates the completion of the I/O operation at the device. The secondary interruption condition is described by the SCSW stored.

When an I/O operation is terminated by HALT SUBCHANNEL but the halt signal is not issued to the device because the device appeared not operational, the subchannel is made status pending with secondary status (and primary status if the subchannel is also subchannel active) with zeros for subchannel and device status.

When TEST SUBCHANNEL is executed and stores an SCSW with the secondary-status bit as one in the IRB, the secondary interruption condition is cleared at the subchannel. The secondary interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

**Status-Pending (Bit 31):** When one, bit 31 indicates that the subchannel is status pending and that information describing the cause of the interruption condition is available to the program. The subchannel becomes status pending whenever intermediate, primary, secondary, or alert status is generated. When

HALT SUBCHANNEL is executed, designating a subchannel that is idle, the subchannel becomes status pending subsequent to performance of the halt function to notify the program that the halt function has been completed. When TEST SUBCHANNEL is executed, thus storing an SCSW with the status-pending bit as one in the IRB, the status-pending condition is cleared at the subchannel. The status-pending condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL. When CLEAR SUBCHANNEL is executed and the designated subchannel is operational, the subchannel becomes status pending subsequent to performance of the clear function to notify the program that the clear function has been completed.

**Note:** The status-pending bit, in conjunction with the remaining bits of the status-control field, indicates the type of status condition. For example, if bits 29 and 31 are ones, the subchannel is status pending with primary status. Alternatively, if only bit 31 is one, then the subchannel is said to be status pending or status pending alone. If only bit 31 is one in the status-control field, the settings of all bits in the subchannel-status and device-status fields are unpredictable. If bit 31 is not one, then the remaining bits of the status-control field are not meaningful.

## CCW-Address Field

Bits 1-31 of word 1 form an absolute address. The address indicated is a function of the subchannel state when the SCSW is stored, as indicated in Figure 16-4 on page 16-19. When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, the CCW-address field is usable for recovery purposes if the CCW-address field-validity flag in the ESW is one.

**Programming Note:** When a CCW address, either detected in the channel-program address (see “Channel-Program Address” on page 15-25) or generated during chaining, would cause the channel subsystem to fetch a CCW from a location greater than  $2^{24} - 1$  while format-0 CCWs are specified for the operation, the invalid address is stored in the CCW-address field of the SCSW without truncation. If the invalid address causes the channel subsystem, while chaining, to fetch a CCW from a location greater than  $2^{31} - 1$  while format-1 CCWs are specified for the operation, the rightmost 31 bits of the invalid address are stored in the CCW-address field.

Subchannel State <sup>1</sup>	CCW Address <sup>2</sup>
Start pending (UUUU0/AIPSX) <sup>3</sup>	Unpredictable
Start pending and device active (UUUU0/AIPSX) <sup>3</sup>	Unpredictable
Subchannel-and-device active (UUUU0/AIPSX) <sup>3</sup>	Unpredictable
Device active only (UUUU0/AIPSX)	Unpredictable
Suspended (YYYYY/AIPSX) <sup>3</sup>	See note 1
Status pending (10001/AIPSX) because of unsolicited alert status from the device while the subchannel was start pending <sup>3</sup>	Channel-program address + 8
Status pending (0Y111/AIPSX) because the device appeared not operational on all paths <sup>3</sup>	Channel-program address + 8
Status pending (10011/AIPSX) because of solicited alert status from the device while the subchannel was start pending and device active <sup>3</sup>	Channel-program address + 8
Status pending (10111/AIPSX) because of solicited alert status generated by the channel subsystem while the subchannel was start pending <sup>3</sup> or start pending and device active <sup>3</sup>	See note 2
Status pending (01001/AIPSX) for the program-controlled-interruption condition while the subchannel was subchannel-and-device active <sup>3</sup>	CCW + 8 of the CCW that contained the last recognized PCI, or 8 higher than a CCW that has subsequently become current
Status pending (01001/AIPSX) for the initial-status-interruption condition while the subchannel was subchannel-and-device active <sup>3</sup>	CCW + 8 of the CCW causing the intermediate interruption condition, or a CCW that has subsequently become current
Status pending (1Y1Y1/AIPSX); termination occurred because of program check caused by one of the following conditions: <sup>3</sup>	
Bit 24 of word 1 of the ORB set to one; incorrect-length-indication-suppression facility not installed	Channel-program address + 8
Unused bits in ORB not set to zeros	Channel-program address + 8
Invalid CCW-address specification in transfer in channel (TIC)	Address of TIC + 8
Invalid CCW-address specification in the channel-program address in the ORB	Channel-program address + 8 <sup>4</sup>

Figure 16-4. (Part 1 of 4) CCW Address as Function of Subchannel State

Subchannel State <sup>1</sup>	CCW Address <sup>2</sup>
Invalid CCW address in TIC	Address of TIC + 8
Invalid CCW address in the channel-program address in the ORB	Channel-program address + 8 <sup>4</sup>
Invalid CCW address while chaining	Invalid CCW address + 8
Invalid command code	Address of invalid CCW + 8 <sup>5</sup>
Invalid count	Address of invalid CCW + 8 <sup>5</sup>
Invalid IDAW-address or MIDAW-address specification	Address of invalid CCW + 8 <sup>5</sup>
Invalid IDAW or MIDAW address in CCW	Address of invalid CCW + 8 <sup>5</sup>
Invalid IDAW address while sequentially fetching IDAWs or invalid MIDAW address while sequentially fetching MIDAWs	Address of current CCW + 8
Invalid data-address specification, format 1	Address of invalid CCW + 8 <sup>5</sup>
Invalid data address in a CCW	Address of invalid CCW + 8 <sup>5</sup>
Invalid data address while sequentially accessing storage	Address of current CCW + 8
Invalid data address in IDAW or MIDAW	Address of current CCW + 8
Invalid IDAW or MIDAW specification	Address of current CCW + 8
Invalid CCW, format 0 or 1, for a CCW other than a TIC	Address of invalid CCW + 8 <sup>5</sup>
Invalid suspend flag – CCW fetched during data chaining has suspend flag set to one	Address of invalid CCW + 8
Invalid suspend flag – CCW has suspend flag set to one, but suspend control was not specified in the ORB	Address of invalid CCW + 8
Invalid MIDA flag – CCW has MIDA flag set to one, but modified-CCW-indirect-data addressing was not specified in the ORB	Address of invalid CCW + 8
Invalid MIDA flag – CCW has MIDA flag set to one and either the skip flag or the IDA flag or both are set to one	Address of invalid CCW + 8
Invalid CCW, format 1, for a TIC	Address of TIC + 8
Invalid sequence ÷ two TICs	Address of second TIC + 8
Invalid sequence ÷ 256 or more CCWs without data transfer	Address of 256th CCW + 8
Status pending (1Y1Y1/AIPSX); termination occurred because of protection check detected as follows: <sup>3</sup>	
On a CCW access	Address of protected CCW + 8 <sup>5</sup>
On data or an IDAW or a MIDAW access	Address of current CCW + 8

Figure 16-4. (Part 2 of 4) CCW Address as Function of Subchannel State

Subchannel State <sup>1</sup>	CCW Address <sup>2</sup>
Status pending (1Y1Y1/AIPSX); termination occurred because of chaining check <sup>3</sup>	Address of current CCW + 8
Status pending (YY1Y1/AIPSX); termination occurred under count control <sup>3</sup>	Address of current CCW + 8 <sup>6</sup>
Status pending (1Y1Y1/AIPSX); operation prematurely terminated by the device because of alert status <sup>3</sup>	Address of current CCW + 8 <sup>6</sup>
Status pending (YYYY1/AIPSX) after termination by HALT SUB-CHANNEL and the activity-control-field bits indicated below set to ones:	
Status pending alone	Unpredictable
Start pending <sup>3</sup>	Unpredictable
Device active and start pending <sup>3</sup>	Unpredictable
Device active	Unpredictable
Subchannel active and device active <sup>3</sup>	CCW + 8 of the last-executed CCW
Suspended	CCW + 8 of CCW causing suspension
Suspended and resume pending	Unpredictable
Status pending (00001/AIPSX) after termination by CLEAR SUB-CHANNEL	Unpredictable
Status pending (YY1Y1/AIPSX); operation completed normally at the subchannel <sup>3</sup>	CCW + 8 of the last-executed CCW <sup>6</sup>
Status pending (00011/AIPSX)	Unpredictable
Status pending (10001/AIPSX)	Unpredictable
Status pending (00001/AIPSX)	Unpredictable
Status pending (1Y111/AIPSX); command chaining suppressed because of alert status other than channel-control check or interface-control check <sup>3</sup>	Address of current CCW + 8 <sup>6</sup>
Status pending (1YYYY/AIPSX) because of alert status for channel-control check or interface-control check <sup>3</sup>	See note 3 <sup>6</sup>
Status pending (1Y1Y1/AIPSX) because of channel-data check <sup>3</sup>	See note 3 <sup>6</sup>

Figure 16-4. (Part 3 of 4) CCW Address as Function of Subchannel State

**Explanation:**

1 The meaning of the notation used in this column is as follows:

- A Alert status
- I Intermediate status
- P Primary status
- S Secondary status
- X Status Pending

The possible combination of status-control-bit settings is shown to the left of the "/" symbol by the use of these symbols:

- 0 Corresponding condition is not indicated
- 1 Corresponding condition is indicated
- U Unpredictable. The corresponding condition is not meaningful when the subchannel is not status pending.
- Y The corresponding condition is not significant and is indicated as a function of the subchannel state.

2 A CCW becomes current when (1) it is the first CCW of a channel program and has been fetched, (2) while command chaining, the previous CCW is no longer current and the new CCW has been fetched, or (3) in the case of data chaining, the new CCW takes over control of the I/O operation (see the section "Data Chaining" in Chapter 15, "Basic I/O Functions"). If chaining is not specified or is suppressed, a CCW is no longer current and becomes the last-executed CCW when secondary status has been accepted by the channel subsystem. During command chaining, a CCW is no longer current when device-end status has been accepted or, in the case of data chaining, when the last byte of data for that CCW has been accepted.

3 The subchannel may also be resume pending.

4 The stored address is the channel-program address (in the ORB) + 8 even though it is either invalid or protected.

5 The stored address is the address of the current CCW + 8 even though it is either invalid or protected.

6 Incorrect length is indicated as a function of the setting of the suppress-length-indication flag in the current CCW (see the section "Channel-Command Word" in Chapter 15, "Basic I/O Functions").

**Notes:**

1. Unless the subchannel is also resume pending, the address stored is the address of the CCW that caused suspension, plus 8. Otherwise, the address stored is unpredictable.
2. The address of the CCW is given as a function of the alert status indicated. For example, if a program-check or protection-check condition is recognized, the CCW address stored is the same as for the entry for program check or protection check, respectively, in this table. Alternatively, if alert status for interface-control check or channel-control check is indicated, the CCW address stored is either the channel-program address (in the ORB) + 8 or invalid as specified by the field-validity flags in the subchannel logout. If alert status for path-verification required is indicated, the CCW address stored is the channel-program address (in the ORB) + 8.
3. Bit 21 of the subchannel-logout information, when stored as one, indicates that the address is CCW + 8 of the last-fetched CCW if the command for the CCW has not been accepted by the device. If the command has been accepted by the device at the time the error condition is recognized, then the address stored is the address of the CCW + 8 of the last-executed CCW.

Figure 16-4. (Part 4 of 4) CCW Address as Function of Subchannel State

## Device-Status Field

Device-status conditions are generated by the I/O device and are presented to the channel subsystem over the channel path. The timing and causes of these conditions for each type of device are specified in the System Library publication for the device. The device-status field is meaningful whenever the subchannel is status pending with any combination of primary, secondary, intermediate, or alert status. Whenever the subchannel is status pending with intermediate status alone, the device-status field is zero. When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, the device-status field is usable for recovery purposes if the device-status field-validity flag in the ESW is one. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the device-status field are not meaningful.

If, within a system, the I/O device is accessible from more than one channel path, status related to channel-subsystem-initiated operations in the single-path mode (solicited status) is signaled over the initiating channel path. Devices operating in the multipath mode may signal solicited status over any channel path that belongs to the same path group as the initiating channel path. The handling of conditions not associated with I/O operations (unsolicited alert status), such as attention, unit exception, and device end due to transition from the not-ready to the ready state, depends on the type of device and condition and is specified in the System Library publication for the device.

The channel subsystem does not modify the status bits received from the I/O device. These bits appear in the SCSW as received over the channel path. For more information on the status bits received from the I/O device, see the publication *ESA/390 Common I/O-Device Commands*, SA22-7204.

## Subchannel-Status Field

Subchannel-status conditions are detected and indicated in the SCSW by the channel subsystem. Except for the conditions caused by equipment malfunctioning, they can occur only while the channel subsystem is involved with the performance of a halt, resume, or start function. The subchannel-status field is meaningful whenever the subchannel is status

Pending with any combination of primary, secondary, intermediate, or alert status. Individual bits contained in the subchannel-status field may be unpredictable even when the subchannel-status field is meaningful. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the subchannel-status field are not meaningful.

## Program-Controlled Interruption

An intermediate interruption condition is generated after a CCW with the program-controlled-interruption (PCI) flag set to one becomes the current CCW. The I/O interruption due to the PCI flag may be delayed an unpredictable amount of time because of masking of the interruption request or other activity in the system. (See “Program-Controlled Interruption” on page 15-34.) When the channel subsystem recognizes an alert interruption condition due to either a channel-control-check condition or an interface-control-check condition, then any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem.

Detection of the PCI condition does not affect the progress of the I/O operation.

## Incorrect Length

Incorrect length occurs when the number of bytes contained in the storage areas assigned for the I/O operation is not equal to the number of bytes requested or offered by the I/O device. Incorrect length is indicated for one of the following reasons:

**Long Block on Input:** During a read, read-backward, or sense operation, the device attempted to transfer one or more bytes to main storage after the assigned main-storage areas were filled, or the device indicated that more data could have been transferred if the count had been larger. The extra bytes have not been placed in main storage. The count in the SCSW is zero.

**Long Block on Output:** During a write or control operation, the device requested one or more bytes from the channel subsystem after the assigned main-storage areas were exhausted, or the device indicated that more data could have been transferred if the count had been larger. The count in the SCSW is zero.

**Short Block on Input:** The number of bytes transferred during a read, read-backward, or sense opera-

tion is insufficient to fill the main-storage areas assigned to the operation. The count in the SCSW is not zero.

**Short Block on Output:** The device terminated a write or control operation before all information contained in the assigned main-storage areas was transferred to the device. The count in the SCSW is not zero.

The incorrect-length indication is suppressed when the current CCW has the SLI flag set to one and the CD flag set to zero. The indication does not occur for operations rejected during the initiation sequence. The indication also does not occur for immediate operations when the count field is nonzero and the subchannel is in the incorrect-length-suppression mode. The incorrect-length indication is not meaningful when the count field of the SCSW is not meaningful.

Presence of the incorrect-length condition suppresses command chaining unless the SLI flag in the CCW is one or unless the condition occurs in an immediate operation when the subchannel is in the incorrect-length-suppression mode.

## Program Check

Program check occurs when programming errors are detected by the channel subsystem. The condition can be due to the following causes:

**Invalid CCW-Address Specification:** The channel-program address (CPA) or the transfer-in-channel command does not designate the CCW on a double-word boundary, or bit 0 of the CPA or bit 32 of a format-1 CCW specifying the transfer-in-channel command is not zero.

**Invalid CCW Address:** The channel subsystem has attempted to fetch a CCW from a main-storage location that is not available. An invalid CCW address can occur because the program has designated an invalid address in the channel-program-address field of the ORB or in the transfer-in-channel command or because, on chaining, the channel subsystem attempts to fetch a CCW from an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute CCW address does not correspond to a physical location.

2. Format-0 CCWs are specified in the ORB, and the absolute CCW address is greater than  $2^{24} - 1$ .

3. Format-1 CCWs are specified in the ORB, and the absolute CCW address is greater than  $2^{31} - 1$ .

**Invalid Command Code:** There are zeros in the four rightmost bit positions of the command code in the CCW designated by the CPA or in a CCW fetched on command chaining. The command code is not tested for validity during data chaining.

**Invalid Count, Format 0:** A CCW, which is other than a CCW specifying transfer in channel, contains zeros in bit positions 48-63.

**Invalid Count, Format 1:** A CCW that specifies data chaining or a CCW fetched while data chaining contains zeros in bit positions 16-31.

**Invalid IDAW-Address or MIDAW-Address Specification:** Indirect data addressing or modified indirect data addressing is specified, and any of the following conditions is detected:

1. The ORB specifies format-1 IDAWs, the CCW specifies indirect data addressing, and the contents of the data-address field in the CCW do not designate the first IDAW on a word boundary; that is, bits 30 and 31 (format-0 CCW) or 62 and 63 (format-1 CCW) are not zeros.
2. The ORB specifies format-2 IDAWs, the CCW specifies indirect data addressing, and the contents of the data-address field in the CCW do not designate the first IDAW on a doubleword boundary; that is, bits 29-31 (format-0 CCW) or 61-63 (format-1 CCW) are not zeros.
3. The ORB specifies modified-CCW-indirect-data addressing, the CCW specifies modified-indirect-data addressing, and the contents of the data-address field in the CCW do not designate the first MIDAW on a quadword boundary.

**Invalid IDAW or MIDAW Address:** The channel subsystem has attempted to fetch an IDAW or MIDAW from a main-storage location that is not available. An invalid IDAW or MIDAW address can occur because the program has designated an invalid address in a CCW that specifies indirect data addressing or modified indirect data addressing, or because the channel subsystem, on sequentially fetching IDAWs or MIDAWs, attempts to fetch from

an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute IDAW or MIDAW address does not correspond to a physical location.
2. Format-0 CCWs are specified in the ORB, and the absolute IDAW or MIDAW address is greater than  $2^{24} - 1$ .
3. Format-1 CCWs are specified in the ORB, and the absolute IDAW or MIDAW address is greater than  $2^{31} - 1$ .

**Invalid Data-Address Specification:** Bit 32 of a format-1 CCW is not zero.

**Invalid Data Address:** When any of the following conditions is detected, an invalid data address is recognized by the channel subsystem.

1. Use of the data address has caused the channel subsystem to attempt to wrap from the maximum storage address to zero.
2. Use of the data address has caused the channel subsystem to attempt to wrap from zero to the maximum storage address during a read-backward operation.
3. The channel subsystem has attempted to transfer data to a storage location that is unavailable.

An invalid data address can occur because the program has designated an unavailable location in a CCW or in an IDAW or MIDAW, or because the channel subsystem, on sequentially accessing storage, attempted to access an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute address of the location does not correspond to a physical location.
2. Format-0 CCWs are specified in the ORB, indirect data addressing is not specified in the CCW, and the absolute address is greater than  $2^{24} - 1$ .
3. Format-1 CCWs are specified in the ORB, indirect data addressing is not specified in the CCW, and the absolute address is greater than  $2^{31} - 1$ .
4. Format-1 IDAWs are specified in the ORB, indirect data addressing is specified in the CCW, and the absolute address is greater than  $2^{31} - 1$ .

5. The absolute address is outside the addressing range specified by SET ADDRESS LIMIT, and the limit mode at the subchannel is active.

**Note:** The maximum storage address is determined as a function of the CCW and IDAW formats used or MIDAWs used. When neither an IDAW nor a MIDAW is used, the maximum storage address is a function of the CCW format specified, as follows:

1. When 24-bit (format 0) CCWs are specified, the maximum storage address recognized by the channel subsystem is  $2^{24} - 1$ .
2. When 31-bit (format 1) CCWs are specified, the maximum storage address recognized by the channel subsystem is  $2^{31} - 1$ .

When an IDAW is used, the maximum storage address is a function of the IDAW format specified, as follows:

1. When 31-bit (format 1) IDAWs are specified, the maximum storage address recognized by the channel subsystem is  $2^{31} - 1$ .
2. When 64-bit (format 2) IDAWs are specified, the maximum storage address recognized by the channel subsystem is  $2^{64} - 1$ .

When a MIDAW is used, the maximum storage address recognized by the channel subsystem is  $2^{64} - 1$ .

**Invalid IDAW or MIDAW Specification:** When any of the following conditions is detected, an invalid IDAW specification is recognized by the channel subsystem:

1. Bit 0 of a format-1 IDAW is not zero.
2. A second or subsequent format-1 IDAW does not designate the location of the beginning byte of a 2K-byte block or, for read-backward operations, the location of the ending byte of a 2K-byte block.
3. A second or subsequent format-2 IDAW does not designate the location of the beginning byte of a 2K-byte or 4K-byte block, as required by the 2K-IDAW control in the ORB, or, for read-backward operations, the location of the ending byte of a 2K-byte or 4K-byte block.

When bit 0 of a format-1 IDAW is not zero, the subchannel is made status pending with program-check

indicated only after the I/O device attempts to transfer data, just as when an invalid data address that refers to a nonexistent data area is detected. If the device ends the operation prior to the transfer of data, no error condition is reported. See “CCW Indirect Data Addressing” in Chapter 15 for additional information about the reporting of program-check conditions.

When any of the following conditions is detected, an invalid MIDAW specification is recognized by the channel subsystem:

1. One or more bits defined as reserved in the MIDAW are not zero.
2. The MIDAW count field contains zeros.
3. The combination of the MIDAW data-address and count fields specify data addresses that cross a 4K-byte block boundary, unless skipping is in effect for the MIDAW.
4. The MIDAW in control has its last-MIDAW flag set to zero and the sum of the count values of the previous MIDAWs in the MIDAL and the MIDAW in control is greater than or equal to the count value in the CCW.
5. The MIDAW in control has its last-MIDAW flag set to one and the sum of the count values in the previous MIDAWs in the MIDAL and the MIDAW in control do not equal the count value in the CCW.
6. The MIDAW in control is a second or subsequent MIDAW whose address is on a 4K-byte boundary.

**Invalid CCW, Format 0:** A CCW other than a CCW specifying transfer in channel does not contain a zero in bit position 39.

**Invalid CCW, Format 1:** A CCW other than a CCW specifying transfer in channel does not contain a zero in bit position 15, or a CCW specifying transfer in channel does not contain zeros in bit positions 0-3 and 8-31.

**Invalid Suspend Flag:** A format-0 or format-1 CCW fetched during data chaining, other than a CCW specifying transfer in channel, does not contain a zero in bit position 38 or 14, respectively. A CCW other than a CCW specifying transfer in channel does not contain a zero in bit position 38 for a format-

0 CCW or bit position 14 for a format-1 CCW, and suspend control was not specified by bit 4 of word 1 of the ORB.

**Invalid MIDA Flag:** When either of the following conditions is detected, an invalid MIDA flag condition is recognized by the channel subsystem.

1. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing; however, modified CCW indirect data addressing was not specified by bit 25 of word 1 of the ORB.
2. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and bit 35 (format 0) or bit 11 (format 1) of the CCW is one, specifying skip.
3. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and bit 37 (format 0) or bit 13 (format 1) of the CCW is one, specifying indirect data addressing.
4. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and the designated subchannel is not associated with channel paths that support modified CCW indirect data addressing.

**Invalid ORB Format:** One or more reserved bit positions in the operation-request block (ORB) is not zero. (See “Operation-Request Block” on page 15-21 for more information.) If the incorrect-length-indication-suppression facility is not installed, then bit 24 of word 1 of the ORB must also be zero.

**Invalid Sequence:** The channel subsystem has fetched two successive CCWs both of which specify transfer in channel, or, depending on the model, a sequence of 256 or more CCWs with command chaining specified was executed by the channel subsystem and did not result in the transfer of any data to or from an I/O device.

Detection of the program-check condition during the initiation of an operation at the device causes the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When the condition is detected after the I/O operation has been initiated at the device, the device is signaled to conclude the operation the next time the device requests or offers a byte of data or

status. In this situation, the subchannel is made status pending as a function of the status received from the device. The program-check condition causes command chaining and command retry to be suppressed.

### **Protection Check**

Protection check occurs when the channel subsystem attempts a storage access that is prohibited by the protection mechanism. Protection applies to the fetching of CCWs, IDAWs, MIDAWs, and output data and to the storing of input data. The subchannel key provided in the ORB is used as the access key for storage accesses associated with an I/O operation.

Detection of the protection-check condition during the fetching of the first CCW, IDAW, or MIDAW causes the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When protection check is detected after the I/O operation has been initiated at the device, the device is signaled to conclude the operation after the available data logically prior to the protection check has been transferred. However, if an access violation occurs when the channel subsystem is in the process of fetching either a new IDAW, MIDAW, or a new CCW while data chaining, and if the device signals the channel-end condition before transferring any data designated by the new CCW, IDAW or MIDAW, then the status is accepted, and the subchannel becomes status pending with primary and alert status and with protection check indicated. Other indications may accompany the protection-check indication as a function of the operation specified by the CCW, the status received from the device, and the current state of the subchannel. The protection-check condition causes command chaining and command retry to be suppressed.

### **Channel-Data Check**

Channel-data check indicates that an uncorrected storage error has been detected in regard to data, contained in main storage, that is currently used in the performance of an I/O operation. The condition may be indicated when detected, even if the data is not used when prefetched. Channel-data check is indicated when data or the associated key has an invalid checking-block code (CBC) in main storage when that data is referenced by the channel subsystem.

On an input operation, when the channel subsystem attempts to store less than a complete checking block, and invalid CBC is detected on the checking block in storage, the contents of the location remain unchanged and with invalid CBC. On an output operation, whenever channel-data check is indicated, no bytes from the checking block with invalid CBC are transferred to the device.

During a storage access, the maximum number of bytes that can be transferred is model dependent. If a channel-data-check condition is recognized during that storage access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. However, the residual count that is stored in the SCSW, when used in conjunction with the storage-access code and the CCW address, designates a byte location within the page in which the channel-data-check condition was recognized.

A condition indicated as channel-data check causes the current operation, if any, to be terminated. The subchannel becomes status pending with primary and alert status, or with primary, secondary, and alert status, as a function of the status received from the device. The count and address fields of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-data-check condition pertains to prefetched data, the failing-storage-address-validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the channel-data-check condition is generated is stored in the ESW failing-storage-address field.

Uncorrectable storage or key errors detected on prefetched data while the subchannel is start pending cause the operation to be canceled before initiation at the device. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-data check indicated, and with the ESW failing-storage address stored.

Whenever channel-data check is indicated, no measurement data for the subchannel is stored.

## Channel-Control Check

Channel-control check is caused by any machine malfunction affecting channel-subsystem controls. The condition includes invalid CBC on a CCW, an IDAW, a MIDAW, or the respective associated key. The condition may be indicated when an invalid CBC is detected on a prefetched CCW, IDAW, MIDAW, or the respective associated key, even if that CCW, IDAW, or MIDAW is not used.

Channel-control check may also indicate that an error has been detected in the information transferred to or from main storage during an I/O operation. However, when this condition is detected, the error has occurred inboard of the channel path: in the channel subsystem or in the path between the channel subsystem and main storage.

Detection of the channel-control-check condition causes the current operation, if any, to be terminated immediately. The subchannel is made status pending with primary and alert status or with primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes a channel-control-check condition, any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem. The count and data-address fields of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-control-check condition pertains to an invalid CBC detected on a prefetched CCW, a prefetched IDAW, a prefetched MIDAW, or the key associated with the prefetched CCW, the prefetched IDAW, or the prefetched MIDAW, an extended-report word with bit 6 set to one, and the failing-storage address, are stored in the ESW when TEST SUBCHANNEL is executed.

Channel-control-check conditions encountered while prefetching when the subchannel is start pending cause the operation to be canceled before initiation at the device. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-control check indicated, and with a failing-storage address that will be stored in the ESW.

If a subchannel is halt pending and the channel subsystem encounters a channel-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending or resume pending and the channel subsystem encounters a channel-control-check condition while performing the start function for that subchannel, the subchannel remains start pending or resume pending unless the channel subsystem can determine that the first command was accepted. The subchannel remains start pending or resume pending even if the channel subsystem was attempting to initiate the I/O operation for the first command and is unable to determine if the command was accepted. If the channel subsystem is unable to determine whether the first command was accepted, the subchannel is made status pending with at least alert and primary status.

In some situations in which a channel-subsystem malfunction exists, the channel-control-check condition may be reported as a machine-check condition.

Whenever channel-control check is indicated, no measurement data for the subchannel is stored.

**Programming Note:** If the status-control field of the SCSW indicates that the subchannel is status pending with alert status but the field-validity flags of the SCSW indicate that the device-status field is not usable for error-recovery purposes, the program should (1) assume that the channel-control-check condition occurred while the channel subsystem was accepting alert status from the device and (2) take the appropriate action for alert status, even though the status itself has been lost.

## Interface-Control Check

Interface-control check indicates that an invalid signal has occurred on the channel path. The condition is detected by the channel subsystem and usually indicates malfunctioning of an I/O device. Interface-control check can occur for any of the following reasons:

1. A data or status byte received from a device while the subchannel is subchannel-and-device

- active or device active has an invalid checking-block code.
2. The status byte received from a device while the subchannel is idle, start pending, suspended, or halt pending has an invalid checking-block code.
  3. A device responded with an address other than the address designated by the channel subsystem during initiation of an operation.
  4. During command chaining, the device appeared not operational.
  5. A signal from an I/O device either did not occur or occurred at an invalid time or had an invalid duration.
  6. The channel subsystem recognized the I/O-error-alert condition (see “I/O-Error Alert (A)” on page 16-36).
  7. ESW bit 26, indicating device-status check, is set to one.

Detection of an interface-control check during a CCW-type IPL I/O operation on a machine that retries IPL I/O operations on an alternate channel path causes the channel subsystem to terminate operations on the current channel path and to retry the IPL I/O operation on another logically-available channel path to the designated device, if one is available, without causing the subchannel to become status-pending. (See “CCW-type IPL” on page 17-17 for additional information.) In all other cases and when an interface-control check has been detected for a CCW-type IPL operation on all logically-available channel paths to the designated device, detection of the interface-control-check condition causes the current operation, if any, to be terminated immediately, and the subchannel is made status pending with alert status, primary and alert status, secondary and alert status, or primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes an interface-control-check condition, any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

If a subchannel is halt pending and the channel subsystem encounters an interface-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending or resume pending and the channel subsystem encounters an interface-control-check condition while performing the start function for that subchannel, the subchannel remains start pending or resume pending unless the channel subsystem can determine that the first command was accepted. The subchannel remains start pending or resume pending even if the channel subsystem was attempting to initiate the I/O operation for the first command and is unable to determine if the command was accepted. If the channel subsystem is unable to determine whether the first command was accepted, the subchannel is made status pending with at least alert and primary status.

If, while initiating a signaling sequence with the channel subsystem for the purpose of presenting status or transferring data, the device presents an address with invalid parity, the error condition is not made available to the program since the identity of the device and associated subchannel are unknown.

Whenever interface-control check is indicated, no measurement data for the subchannel is stored.

**Programming Note:** If the status-control field of the SCSW indicates that the subchannel is status pending with alert status but the field-validity flags of the SCSW indicate that the device-status field is not usable for error-recovery purposes, the program should (1) assume that the interface-control-check condition occurred while the channel subsystem was accepting alert status from the device and (2) take the appropriate action for alert status, even though the status itself has been lost.

### Chaining Check

Chaining check is caused by channel-subsystem overrun during data chaining on input operations. The condition occurs when the I/O-data rate is too high for the particular resolution of data addresses. Chaining check cannot occur on output operations.

Detection of the chaining-check condition causes the I/O device to be signaled to conclude the operation. It causes command chaining to be suppressed.

## Count Field

Bit positions 16-31 of word 2 contain the residual count. The count is to be used in conjunction with the original count specified in the last CCW and, depending upon existing conditions (see Figure 16-5 on page 16-31), indicates the number of bytes trans-

ferred to or from the area designated by the CCW. The count field is meaningful whenever the subchannel is status pending with primary status that consists of either (1) device status only or (2) device status together with subchannel status of incorrect length only, PCI only, or both.

In Figure 16-5 on page 16-31, the contents of the count field are listed for all cases where the subchannel is start pending, subchannel-and-device active, device active, suspended, or status pending.

Subchannel State <sup>1</sup>	Count <sup>2</sup>
Start pending (UUUU0/AIPSX) <sup>2</sup>	Not meaningful <sup>3</sup>
Start pending and status pending (10YY1/AIPSX) <sup>2</sup>	Not meaningful <sup>3</sup>
Start pending and status pending (00111/AIPSX) because the device appeared not operational on all paths <sup>2</sup>	Not meaningful <sup>3</sup>
Start pending and device active (UUUU0/AIPSX) <sup>2</sup>	Not meaningful <sup>3</sup>
Suspended (YYYYY/AIPSX) <sup>2</sup>	Not meaningful <sup>3</sup>
Subchannel-and-device active (UUUU0/AIPSX) <sup>2</sup>	Not meaningful <sup>3</sup>
Device active (UUUU0/AIPSX)	Not meaningful <sup>3</sup>
Status pending (01001/AIPSX) because of program-controlled-interruption condition or initial-status interruption	Not meaningful <sup>3</sup>
Status pending (1Y1Y1/AIPSX); termination occurred because of: <sup>2</sup>	
Program check	Not meaningful <sup>3</sup>
Protection check	Not meaningful <sup>3</sup>
Chaining check	Not meaningful <sup>3</sup>
channel-control check	See note 1
Interface-control check	Not meaningful <sup>3</sup>
Channel-data check	See note 2
Status pending (YY1Y1/AIPSX); termination occurred under count control <sup>2</sup>	Correct
Status pending (Y0011/AIPSX) <sup>2</sup>	Not meaningful <sup>3</sup>
Status pending (1Y1Y1/AIPSX) <sup>2</sup>	Correct; residual count of last used CCW
Status pending (1Y111/AIPSX); command chaining suppressed because of alert status <sup>2</sup>	Correct; residual count of last used CCW
Status pending (YYYY1/AIPSX); after termination by HALT SUBCHANNEL <sup>2</sup>	Unpredictable
Status pending (00001/AIPSX); after termination by CLEAR SUBCHANNEL	Not meaningful <sup>3</sup>
Status pending (YY1Y1/AIPSX); operation completed normally at the subchannel <sup>2</sup>	Correct; indicates the residual count
Status pending (1Y111/AIPSX); command chaining terminated because of alert status <sup>2</sup>	Correct; original count of CCW specifying the new I/O operation
Status pending (10001/AIPSX) because of alert status	Not meaningful <sup>3</sup>

Figure 16-5. (Part 1 of 2) Contents of Count Field in SCSW

**Explanation:**

- <sup>1</sup> In situations where more than a single condition exists because of, for example, alert status that is described by program check and unit check, the entry appearing first in the table takes precedence.

The meaning of the notation used in this column is as follows:

- A Alert status
- I Intermediate status
- P Primary status
- S Secondary status
- X Status Pending

The allowed combinations of status-control-bit settings is shown to the left of the "/" symbol by the use of these symbols:

- 0 Corresponding condition is not indicated
- 1 Corresponding condition is indicated
- U Unpredictable. The corresponding condition is not meaningful when the subchannel is not status pending.
- Y The corresponding condition is not significant and is indicated as a function of the subchannel state.

- <sup>2</sup> The subchannel may also be resume pending.

- <sup>3</sup> The contents of the count field are not meaningful because the count field is not valid when the SCSW is stored and the subchannel is in the given state.

**Notes:**

1. The count is unpredictable unless IDAW/MIDAW check is indicated, in which case the count may not correctly reflect the number of bytes transferred to or from main storage but will (when used in conjunction with the CCW address) designate a byte location within the page in which the channel-control-check condition was recognized.
2. During a storage access, the maximum number of bytes that can be stored by a channel subsystem is model dependent. If a channel-data-check condition is recognized during that access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. However, the residual count that is stored when used in conjunction with the storage-access code and the CCW address designates a byte location within the page in which the channel-data-check condition was recognized.

Figure 16-5. (Part 2 of 2) Contents of Count Field in SCSW

## Extended-Status Word

The extended-status word (ESW) provides additional information to the program about the subchannel and its associated device. The ESW is placed in words 3-7 of the IRB designated by the second operand of TEST SUBCHANNEL when TEST SUBCHANNEL is executed and the subchannel designated is operational. If the subchannel is status pending or status pending with any combination of primary, secondary, intermediate, or alert status (except as noted in the next paragraph) when TEST SUBCHANNEL is executed, the ESW may have any of the following types of extended-status format:

- Format 0* Subchannel logout in word 0, an ERW in word 1, a failing-storage address or zeros in words 2 and 3, and a secondary-CCW address or zeros in word 4.
- Format 1* Zeros in bytes 0, 2, and 3 of word 0, the LPUM in byte 1 of word 0, an ERW in word 1, and zeros in words 2-4.
- Format 2* Zeros in byte 0, the LPUM in byte 1, and the device-connect time in bytes 2 and 3 of word 0; an ERW in word 1; zeros in words 2-4.
- Format 3* Zeros in byte 0, the LPUM in byte 1, and unpredictable values in bytes 2 and 3 of word 0; an ERW in word 1; zeros in words 2-4.

Words 0-4 of the ESW contain unpredictable values if any of the following conditions is met:

1. The subchannel is not status pending.
2. The subchannel is status pending alone, and the extended-status-word-format bit is zero.
3. The subchannel is status pending with intermediate status alone for other than the intermediate interruption condition due to suspension.

The type of extended-status format stored depends upon conditions existing at the subchannel at the time TEST SUBCHANNEL is executed. The conditions under which each of the types of formats is stored are described in the remainder of this section.

## Extended-Status Format 0

The ESW stored by TEST SUBCHANNEL is a format-0 ESW when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is one and the subchannel is status pending with any combination of status as defined in Figure 16-6 on page 16-37. In this case, subchannel-logout information and an ERW are stored in the extended-status word. Subchannel logout provides detailed model-independent information relating to a subchannel and describing equipment errors detected by the channel subsystem. The information is provided to aid the recovery of an I/O operation, a device, or both. Whenever subchannel logout is provided, the error conditions relate only to the subchannel reporting the error. If I/O operations involving other subchannels have been affected by the error condition, those subchannels also provide similar subchannel-logout information. An extended-report word provides additional information relating to the cause of the malfunction.

A format-0 ESW has the following format:

Word

0	Subchannel Logout
1	Extended-Report Word
2	Failing-Storage Address or ESLD
3	
4	Secondary-CCW Address

0

31

## Subchannel Logout

The subchannel logout has the following format:

0	ESF	LPUM	R	FVF	SA	TC	DEA	SC		
1			8		16	22	24	26	29	31

**Extended-Status Flags (ESF):** Any of bits 1-7, when one, specifies that an error-check condition has been detected by the channel subsystem. The following indications are provided in the ESF field:

**Key Check.** Bit 1, when one, indicates that the channel subsystem, when accessing data, when attempting to update the measurement block, or when attempting to fetch either a CCW, an IDAW, or a MIDAW, has detected an invalid checking-block code (CBC) on the associated storage key. The channel-data-check bit, bit 12 of word 2 of the SCSW, the measurement-block data-check

bit, bit 3 of word 0 of the ESW, the CCW-check bit, bit 5 of word 0 of the ESW, or the IDAW/MIDAW-check bit, bit 6 of word 0 of the ESW, identifies the source of the key error.

**Note:** This condition may be indicated to the program when an invalid checking-block code on a key is detected but the data, CCW, IDAW, or MIDAW then is not used after being prefetched. In this case, the failing-storage-address-validity bit, bit 6 of the ERW, is one, indicating that the address of a location within the storage block having the key is stored in words 2 and 3 of the ESW.

*Measurement-Block Program Check.* Bit 2, when one, indicates that the channel subsystem, in attempting to update the measurement block, has either detected an invalid absolute address when combining the measurement-block origin with the measurement-block index for this subchannel or has detected an invalid measurement-block address at the subchannel.

*Measurement-Block Data Check.* Bit 3, when one, indicates that a malfunction has been detected involving the data of the measurement block in main storage. (See “Measurement Block” on page 17-3.) Measurement-block data check is indicated when the measurement block is updated and an invalid checking-block code (CBC) is detected on the storage used to contain the measurement data or on the associated key. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also stored as one.

*Measurement-Block Protection Check.* Bit 4, when one, indicates that the channel subsystem, when attempting to update the measurement block, has been prohibited from accessing the measurement block because the storage key does not match the measurement-block key (see “Measurement Block” on page 17-3.) The key provided by SET CHANNEL MONITOR is used for the access of storage associated with measurement-block-update operations (see “SET CHANNEL MONITOR” on page 14-13.).

**Note:** Whenever any of the measurement-check conditions is indicated by bits 2-4, the channel subsystem sets the subchannel measurement-block-update-enable bit to zero, disabling the storing of measurement data for the subchannel

(see “Measurement-Mode Enable (MM)” on page 15-3).

*CCW Check.* Bit 5, when one, indicates that an invalid CBC on the contents of the CCW or its associated key has been detected. When either of these conditions is detected, the I/O operation is terminated, the subchannel becomes status pending with primary and alert status, the extended-status-word-format bit in the SCSW is stored as one, and channel-control check is indicated in the subchannel-status field. The subchannel also becomes status pending with secondary status as a function of the type of termination or status received from the device. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also stored as one.

**Note:** This condition may be indicated to the program when an invalid checking-block code on a prefetched CCW is detected but the CCW is not used. In this case, the failing-storage-address-validity bit, bit 6 of the ERW, is one, indicating that the address of a location having the invalid CBC is stored in words 2 and 3 of the ESW.

*IDAW/MIDAW Check.* Bit 6, when one, indicates that an invalid CBC on the contents of an IDAW or MIDAW or its associated key has been detected. When either of these conditions is detected, the I/O operation is terminated with the device, the subchannel becomes status pending with primary and alert status, the extended-status-word-format bit in the SCSW is one, and channel-control check is indicated in the subchannel-status field. The subchannel also becomes status pending with secondary status as a function of the type of termination or status received from the device. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also one.

**Note:** This condition may be indicated to the program when an invalid checking-block code on the contents of a prefetched IDAW or MIDAW is detected but the IDAW or MIDAW is not used. In this case, the failing-storage-address-validity bit, bit 6 of the ERW, is one, indicating that the address of a location having the invalid CBC is stored in words 2 and 3 of the ESW. Detection of a channel-data-check condition does not cause the CCW-check and IDAW/MIDAW-check bits to be stored as ones.

*Reserved.* Bit 7 is stored as zero.

**Last-Path-Used Mask (LPUM):** Bits 8-15 indicate the channel path that was last used for communicating or transferring information between the channel subsystem and the device. The bit corresponding to the channel path in use is set whenever any of the following occurs:

1. The first command of a start-subchannel function is accepted by the device (see “Activity Control (AC)” on page 16-13).
2. The device and channel subsystem are actively communicating when the channel subsystem performs the suspend function for the channel program in execution.
3. The channel subsystem accepts status from the device that is recognized as an interruption condition, or a condition has been recognized that suppresses command chaining (see “Interruption Conditions” on page 16-1).
4. The channel subsystem recognizes an interface-control-check condition (see “Interface-Control Check” on page 16-28), and no subchannel-logout information is currently present at the subchannel.

The LPUM field contains the most recent setting and is valid whenever the ESW contains information in one of the formats 0-3 (see “Extended-Status Word” on page 16-33) and the SCSW is stored. When subchannel-logout information is present in the ESW, a zero LPUM-field-validity flag indicates that the LPUM setting is not consistent with the other subchannel-logout indications.

**Ancillary Report (R):** Bit 16, when one, indicates that a malfunction of a system component has occurred that has been recognized previously or that has affected the activities of multiple subchannels. When the malfunction affects the activities of multiple subchannels, an ancillary-report condition is recognized for all of the affected subchannels except one. This bit, when zero, indicates that this malfunction of a system component has not been recognized previously. This bit is meaningful only when a channel-control check, channel-data check, or an interface-control check is indicated in bit positions 12-14 of word 2 of the SCSW.

Depending on the model, recognition of an ancillary-report condition may not be provided or it may not be

provided for all system malfunctions that effect sub-channel activity. When ancillary-report recognition is not provided, bit 16 is set to zero

**Field-Validity Flags (FVF):** Bits 17-21 indicate the validity of the information stored in the corresponding fields of either the SCSW or the extended-status word. When the validity bit is one, the corresponding field has been stored and is usable for recovery purposes. When the validity bit is zero, the corresponding field is not usable.

This bit-significant field has meaning when channel-data check, channel-control check, or interface-control check is indicated in the SCSW. When these checks are not indicated, this field, as well as the termination-code and sequence-code fields, has no meaning. Furthermore, when these checks are not indicated, the last-path-used-mask, device-status, and CCW-address fields are all valid. The fields are defined as follows:

- 17 Last-path-used mask
- 18 Termination code
- 19 Sequence code
- 20 Device status
- 21 CCW address

**Storage-Access Code (SA):** Bits 22-23 indicate the type of storage access that was being performed by the channel subsystem at the time of error. The SA field pertains only to the access of storage for the purpose of fetching or storing data during the performance of an I/O operation. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the subchannel status. The access-code assignments are as follows:

- 00 Access type unknown
- 01 Read
- 10 Write
- 11 Read backward

**Termination Code (TC):** Bits 24 and 25 indicate the type of termination that has occurred. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the SCSW. The types of termination are as follows:

- 00 Halt signal issued
- 01 Stop, stack, or normal termination
- 10 Clear signal issued

## 11 Reserved

When at least one channel check is indicated in the SCSW but the termination-code-field-validity flag is zero, it is unpredictable which, if any, termination has been signaled to the device. If more than one channel-check condition is indicated in the SCSW, the device may have been signaled one or more termination codes that are the same or different. In this situation, if the termination-code-field-validity flag is one, the termination code indicates the most severe of the terminations signaled to the device. The termination codes, in order of increasing severity, are: stop, stack, or normal termination (01); halt signal issued (00); and clear signal issued (10).

**Device-Status Check (D):** When the status-verification facility is installed, bit 26, when one, indicates that the subchannel logout in the ESW resulted from the channel subsystem detecting device status that had valid CBC but that contained a combination of bits that was inappropriate when the status byte was presented to the channel subsystem. When the device-status-check bit is one, the interface-control-check status bit is set to one. If, additionally, bit 20 of the subchannel-logout field has been stored as one, then the status byte in error has been stored in the device-status field of the SCSW. If the status-verification facility is not installed, bit 26 is stored as zero.

**Secondary Error (E):** Bit 27, when one, indicates that a malfunction of a system component that may or may not have been directly related to any activity involving subchannels or I/O devices has occurred. Subsequent to this occurrence, the activity related to this subchannel and the associated I/O device was affected and caused the subchannel to be set status pending with either channel-control check or interface-control check.

**I/O-Error Alert (A):** Bit 28, when one, indicates that subchannel logout in the ESW resulted from the signaling of I/O-error alert. The I/O-error-alert signal indicates that the control unit or device has detected a malfunction that must be reported to the channel subsystem. The channel subsystem, in response, issues a clear signal and, except as described in the next paragraph, causes interface-control check to be set and extended-status-format-0 (logout) information to be stored in the ESW.

When I/O-error alert is signaled and the subchannel has previously been set disabled or no subchannel is associated with the device, the clear signal is issued

to the device, and the I/O-error-alert indication is ignored by the channel subsystem.

**Sequence Code (SC):** Bits 29-31 identify the I/O sequence in progress at the time of error. The sequence code pertains only to I/O operations initiated by the execution of START SUBCHANNEL or RESUME SUBCHANNEL. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the SCSW.

The sequence-code assignments are:

000 Reserved

- 001 A nonzero command byte has been sent by the channel subsystem, but a response has not yet been analyzed by the channel subsystem. This code is set during the initiation sequence.
- 010 The command has been accepted by the device, but no data has been transferred.
- 011 At least one byte of data has been transferred between the channel subsystem and the device. This code may be used when the channel path is in an idle or polling state.

- 100 The command in the current CCW (1) has not yet been sent to the device, (2) was sent but not accepted by the device, or (3) was sent and accepted but command-retry status was presented. This code is set when any of the following conditions occurs:
1. The command address is updated during command chaining or during the initiation of a start function or resume function at the device.
  2. During the initiation sequence, the status includes attention, control unit end, unit check, unit exception, busy, status modifier (without channel end and device end), or device end (without channel end).
  3. Command retry is signaled.
  4. The channel subsystem interrogates the device in the process of clearing an interruption condition.
  5. The channel subsystem signals the conclusion of the chain of operations to the device during command chaining while performing the suspend function.
- 101 The command in the current CCW has been accepted, but data transfer is unpredictable. This code applies from the time a device is logically connected to a channel path until the time it is determined that a new sequence code applies. This code may also be used when the channel subsystem places a channel path in the polling or idle state and it is impossible to determine that code 010 or 011 applies. It may also be used at other times when a channel path cannot distinguish between code 010 or 011.
- 110 Reserved.
- 111 Reserved.

Figure 16-6 on page 16-37 defines the relationship between indications provided as subchannel-logout data and the appropriate SCSW bits.

Subchannel-Logout Condition Indicated	Logout Condition for SCSW Indication of <sup>1</sup>		
	CDC	CCC	IFCC
Key check	V	V	-
Measurement-block-program check <sup>2</sup>	-	-	-
Measurement-block-data check <sup>2</sup>	-	-	-
Measurement-block-protection check <sup>2</sup>	-	-	-
CCW check	-	V	-
IDAW/MIDAW check	-	V	-
Last-path-used mask <sup>3</sup>	V	V	V
Field-validity flags	V	V	V
Termination code <sup>3</sup>	V	V	V
Device-status check	-	-	V
Secondary error	-	V	V
I/O-error alert	-	-	V
Sequence code <sup>3</sup>	V	V	V

**Explanation:**

- No relationship.  
<sup>1</sup> When more than one SCSW indication is signaled, the subchannel-logout conditions that are valid are the logical OR for each of the respective SCSW indications.  
<sup>2</sup> Only one measurement-block check may be indicated in a specific subchannel logout.  
<sup>3</sup> This field has a field-validity flag.  
 CCC Channel-control check.  
 CDC Channel-data check.  
 IFCC Interface-control check.  
 V Bit setting valid.

Figure 16-6. Relationship Between Subchannel-Logout Data and SCSW Bits

## Extended-Report Word

The extended-report word (ERW) provides information to the program describing specific conditions that may exist at the device, subchannel, or channel subsystem. The ERW is stored whenever the extended-status word is stored. When the extended-status-word-format bit, bit 5 of word 0 of the SCSW, and the extended-control bit, bit 14 of word 0 of the SCSW, are both zeros, the ERW contains all zeros. When the extended-status-word-format bit or the extended-control bit or both are ones, the ERW has the following format:

**Request Logging Only (L) :** Bit 1, when one, requests that the program only record information about the condition that caused the extended-status word to be stored.

**Extended-Subchannel-Logout Pending (E):** Bit 2, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that an extended-subchannel logout is pending and that words 2-3 of the ESW contain the extended-subchannel-logout descriptor.

Bit 2 is set to zero when bit 6 is set to one.

When an ERW is stored with bits 2 and 6 both set to zero, zeros are stored in words 2 and 3 of the ESW.

**Authorization Check (A):** Bit 3, when one, indicates that the start or resume function was terminated because the channel subsystem has been placed in the isolated state in which pending I/O operations are not initiated and I/O operations currently being performed either are in the process of being terminated or have been terminated.

**Path Verification Required (P):** Bit 4, when one, indicates that the program must verify the identity of the device. The LPUM, when valid, indicates the channel path for which device verification is to be performed. When a valid LPUM is not available, the identity of the device must be verified for each available channel path.

**Channel-Path Timeout (T):** Bit 5, when one, indicates that, during a signaling sequence, an appropriate signal from the device did not occur within a predetermined time interval. Bit 5 is meaningful when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, and the interface-control-check bit, bit 14 of word 2 of the SCSW, are both ones.

**Failing-Storage-Address Validity (F):** Bit 6, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that the channel subsystem has detected an invalid CBC on a CCW, a data location, an IDAW, a MIDAW or the respective associated key and has stored, in words 2 and 3 of the ESW, the absolute address of a location associated with the invalid CBC.

Bit 6 is set to zero when bit 2 is set to one.

When an ERW is stored with bits 2 and 6 both set to zero, zeros are stored in words 2 and 3 of the ESW.

**Concurrent Sense (S) :** Bit 7, when one, indicates that the concurrent-sense facility has placed sense information accepted from the device in the extended-control word and has stored a value, in bit positions 10-15 of the ERW, that specifies the number of sense bytes that have been stored in the extended-control word. When bit 7 is one, bit 14 of word 0 of the SCSW is also one.

**Concurrent-Sense Count (SCNT):** When bit 7 is one, bit positions 10-15 contain a value, in the range 1-32, that specifies the number of sense bytes stored into the extended-control word by the concurrent-sense facility. When bit 7 is zero, bit positions 10-15 contain zeros.

**Secondary-CCW-Address Validity (C):** Bit 8, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that the channel subsystem has detected an error condition that precludes the continued performance of an I/O operation. When prefetching applies (bit 9 of word 1 of the ORB is one) and certain error conditions identified by channel-control check, channel-data check, or interface-control check are recognized by the channel subsystem, situations may exist where the termination point of execution of the channel program differs between the channel subsystem and the I/O device. To properly identify the termination points, bit 8 is set to one, and a second CCW address (secondary-CCW address) is provided in the ESW and designates the last CCW executed at the device. When the validity bit is zero for the previously mentioned errors, the channel subsystem was unable to determine the termination point of the control-unit execution, and the secondary-CCW-address field contains zeros.

Bit 8 is not set to one unless the program has permitted prefetching by setting the prefetch-control bit, bit 9 of word 1 of the ORB, to one for the channel program in execution.

**Failing-Storage-Address Format (R):** Bit 9 indicates the format of the failing-storage address when the failing-storage-address validity bit, bit 6 of the ERW, is one. When bit 6 is zero, bit 9 is not meaningful and is stored as zero. When bit 6 is one and bit 9 is zero, a format-1 failing-storage address is stored in words 2 and 3 of the ESW. When bit 6 is one and bit 9 is one, a format-2 failing-storage address is stored in words 2 and 3. See "Failing-Storage Address" below for a description of format-1 and format-2 addresses.

## Failing-Storage Address

Words 2 and 3 of the extended-status contain a 24-, 31-, or 64-bit absolute address. When the failing-storage-address-validity flag, bit 6 of the ERW, is one, words 2 and 3 contain either a format-1 failing-storage address or a format-2 failing-storage address. When bit 6 is one, the failing-storage-address field designates a byte location within the invalid checking block associated with an invalid CBC for a CCW, data location, IDAW, MIDAW, or their respective associated key.

When an error condition is detected, the form of the address stored in words 2 and 3 depends on the format-2-IDAW control, bit 14 of word 1 of the ORB, and on the MIDA control, bit 25 of word 1 of the ORB, as follows:

1. When the format-2-IDAW control is zero, specifying that fullword IDAWs containing 31-bit addresses are used, and the modified-CCW-indirect-data-addressing-control is zero, a format-1 address is stored, and the failing-storage-address-format bit, bit 9 of the ERW, is stored as zero.
2. When either the format-2-IDAW control is one, specifying that doubleword IDAWs containing 64-bit addresses are used, or the modified-CCW-indirect-data-addressing-control is one, or both are one, a format-2 address is stored, and the failing-storage-address-format bit is stored as one.

When a format-1 address is stored, bits 1-31 of word 2 form the address associated with the reported error condition, and bit 0 of word 2 and all of word 3 are stored as zeros. When a format-2 address is stored, bits 0-31 of word 2 followed by bits 0-31 of word 3 form the 64-bit address associated with the reported error condition.

## Extended-Subchannel-Logout Descriptor (ESLD)

When the extended-status-word-format (L) bit, bit 5 of SCSW word 0, is one and the extended-subchannel-logout pending (E) flag, bit 2 of the ERW, is one, an extended-subchannel-logout descriptor is provided in words 2-3 of the ESW. The ESLD identifies the logout and the channel path for which the extended-subchannel logout is pending.

## Secondary-CCW Address

When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check and the secondary-CCW-address-validity flag, bit 8 of word 1, is one, bits 1-31 of word 4 form an absolute address of the last CCW executed by the I/O device at the point the reported check condition caused channel-program termination. When provided, the secondary-CCW address may be used for recovery purposes. When the secondary-CCW-address-validity flag is zero, this field contains zeros.

## Extended-Status Format 1

The ESW stored by TEST SUBCHANNEL is a format-1 ESW when all of the following conditions are met:

1. The extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero.
2. The subchannel status-control field has the status-pending bit, bit 31 of word 0 of the SCSW, set to one, together with:
  - a. The primary-status bit, bit 29 of word 0 of the SCSW, alone,
  - b. The primary-status bit and other status-control bits, or
  - c. The intermediate-status bit, bit 28 of word 0 of the SCSW, and the suspended bit, bit 26 of word 0 of the SCSW.
3. At least one of the following conditions is indicated:
  - a. The device-connect-time-measurement mode is inactive.
  - b. The channel-subsystem-timing facility is not available for the subchannel.
  - c. The subchannel is not enabled for the device-connect-time-measurement mode.

Zeros are stored in bytes 0, 2, and 3 of word 0, and the LPUM is stored in byte 1 of word 0; an ERW is stored in word 1; zeros are stored in words 2-4.

The device-connect-time-measurement mode is made inactive when SET CHANNEL MONITOR is executed and bit 31 of general register 1 is zero.

A format-1 ESW has the following format:

Word	Format-1 ESW		
0	Zeros	LPUM	Zeros
1	Extended-Report Word		
2			
3	Zeros		
4			
	0	8	16
			31

**Last-Path-Used Mask (LPUM):** For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 16-35.

**Extended-Report Word (ERW):** For a definition of the ERW, see “Extended-Report Word” on page 16-37.

## Extended-Status Format 2

The ESW stored by TEST SUBCHANNEL is a format-2 ESW when all of the following conditions are met:

1. The extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero.
2. The channel-subsystem-timing facility is available for the subchannel.
3. The subchannel is enabled for the device-connect-time-measurement mode.
4. The device-connect-time-measurement mode is active.
5. The subchannel status-control field has the status-pending bit, bit 31 of word 0 of the SCSW, set to one, together with:
  - a. The primary-status bit, bit 29 of word 0 of the SCSW, alone,
  - b. The primary-status bit and other status-control bits, or
  - c. The intermediate-status bit, bit 28 of word 0 of the SCSW, and the suspended bit, bit 26 of word 0 of the SCSW.

Zeros are stored in byte 0 of word 0, the LPUM is stored in byte 1 of word 0, and the device-connect time is stored in bytes 2 and 3 of word 0; an ERW is stored in word 1; zeros are stored in words 2-4.

A format-2 ESW has the following format:

Word	Format-2 ESW		
0	Zeros	LPUM	DCTI
1	Extended-Report Word		
2			
3	Zeros		
4			
	0	8	16
			31

**Last-Path-Used Mask (LPUM):** For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 16-35.

**Device-Connect-Time Interval (DCTI):** Bit positions 16-31 contain the binary count of time increments accumulated by the channel subsystem during the time that the channel subsystem and the device were actively communicating and the subchannel was subchannel active. The time increment of the DCTI is 128 microseconds.

If the above conditions for the storing of the DCTI value in the ESW are met but the device-connect-time-measurement mode was made active by SET CHANNEL MONITOR subsequent to the execution of START SUBCHANNEL for this subchannel, the DCTI value stored is greater than or equal to zero and less than or equal to the correct DCTI value.

**Note:** The DCTI value stored in the ESW is the same as that used to update the corresponding measurement-block data for the subchannel if the measurement-block-update mode is in use for the subchannel. If the measurement-block-update mode for the channel subsystem is active and the subchannel is enabled for the device-connect-time-measurement mode but no DCTI value is stored in the ESW (because of the presence of subchannel-logout information), or if the DCTI is zero, then nothing is added to the corresponding measurement-block data.

**Extended-Report Word (ERW):** For a definition of the ERW, see “Extended-Report Word” on page 16-37.

## Extended-Status Format 3

The ESW stored by TEST SUBCHANNEL is a format-3 ESW when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero and the subchannel is status pending with (1) secondary status,

alert status, or both when primary status is not also present, or (2) intermediate status when the subchannel is not suspended. Zeros are stored in byte 0 of word 0, and the LPUM is stored in byte 1 of word 0. Bytes 2 and 3 of word 0 contain unpredictable values; an ERW is stored in word 1; zeros are stored in words 2-4.

A format-3 ESW has the following format:

#### Word

0	Zeros	LPUM	X X X X X X X X X X X X X X X X
1	Extended-Report Word		
2			
3	Zeros		
4	0	8	16
			31

**Last-Path-Used Mask (LPUM):** For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 16-35.

An “X” in the format indicates the bit may be zero or one.

**Extended-Report Word (ERW):** For a definition of the ERW, see “Extended-Report Word” on page 16-37.

Figure 16-7 on page 16-41 summarizes the conditions at the subchannel under which each type of information is stored in the ESW.

Subchannel Conditions When IRB is stored						Extended-Status Word (ESW), Word 0	
Subchannel-Status Word				Path-Management-Control Word		Format	Content Bytes 0,1,2,3
Status-Control Field	L Bit	Suspended Bit	Device Connect-Time-Msrmnt Mode	Timing-Facility Bit	Device-Connect-Time-Msrmnt-Mode-Enable Bit		
---0	/	/	/	/	/	/	/
00001	0	/	/	/	/	/	/
01001	0	0	Inactive	/	/	/	/
		1	Active	0	0	1	2
**1*1	0	///	Inactive	/	/	/	1
		///		0	0	1	2
**011	0	///	Active	1	1	1	ZMDD
1*001	0	///					3
***1	1	///					ZM**
		///					0
		///					RRRR

**Explanation:**

- Defined to be not meaningful when X is zero.
- \* Bits may be zeros or ones.
- / Information not relevant in this situation.
- A Alert status.
- D Accumulated device-connect-time-interval (DCTI) value stored in bytes 2 and 3.
- I Intermediate status.
- L Extended-status-word format.
- M Last-path-used mask (LPUM) stored in byte 1.
- P Primary status.
- R Subchannel-logout information stored in word 0.
- S Secondary status.
- U No format defined.
- X Status pending.
- Z Bits are stored as zeros.

Figure 16-7. Information Stored in ESW

## Extended-Control Word

The extended-control word, which is words 8-15 of an interruption-response block (see “Interruption-Response Block” on page 16-6), provides additional information to the program describing conditions that may exist at the channel subsystem, subchannel, or device. The extended-control (E) bit, bit 14 of word 0 of the SCSW, when one, indicates that model-depen-

dent information or concurrent-sense information has been stored in the extended-control word.

The information provided in the extended-control word is as follows:

SCSW Bits		ERW Bit 7	ERW Bits 10-15	ECW Words 0-7
5	14			
0	0	0	Zeros	Unpredictable <sup>1</sup>
0	1	0	( <sup>5</sup> )	( <sup>5</sup> )
0	1	1	( <sup>3</sup> )	Concurrent-sense information <sup>4</sup>
1	0	0	Zeros	Unpredictable <sup>1</sup>
1	1	0	Zeros	Model-dependent information <sup>2</sup>
1	1	1	( <sup>3</sup> )	Concurrent-sense information <sup>4</sup>

**Explanation:**

<sup>1</sup> If stored, the value of these words is unpredictable.  
<sup>2</sup> Unused bits in the model-dependent information are stored as zeros.  
<sup>3</sup> Bit positions 10-15 contain a value equal to the number of sense bytes returned.  
<sup>4</sup> Unused bytes in the concurrent-sense information are stored as zeros.  
<sup>5</sup> The combination of SCSW bit 5 as 0, SCSW bit 14 as one, and ERW bit 7 as zero does not occur.

## Extended-Measurement Word

The extended-measurement word (EMW) provides I/O measurement information to the program for the most recent start or resume operation performed at the subchannel. When the extended-I/O-measurement-word facility is installed and enabled, the EMW is conditionally stored in words 16-23 of the IRB designated by the second operand of TEST SUBCHANNEL when TEST SUBCHANNEL is executed. The EMW is stored by TEST SUBCHANNEL when all of the following conditions are met:

1. The extended-status-word-format (L) bit (bit 5, word 0 of the SCSW) is zero.
2. The channel-subsystem-timing facility is available for the subchannel, as indicated by the timing facility bit (T) at the subchannel.
3. The extended-I/O-measurement-word-mode enable bit (X) at the subchannel is one.

4. The subchannel status-control field has the status-pending bit (bit 31, word 0 of the SCSW) set to one, together with:

- a. The primary-status bit (bit 29, word 0 of the SCSW) alone, or
- b. The primary-status bit and other status-control bits, or
- c. The secondary-status bit (bit 29, word 0 of the SCSW) alone, or
- d. The intermediate-status bit (bit 28, word 0 of the SCSW) and the suspended bit (bit 26, word 0 of the SCSW).

Words 16-23 of the IRB contain unpredictable values when the extended-I/O-measurement-word facility is installed and enabled but the conditions listed above are not met.

When the extended-I/O-measurement-word facility is not installed, or the facility is installed but not enabled, words 16-23 of the IRB are not accessed by the channel subsystem.

The format of the extended-measurement word is shown below:

Word	
0	Device-Connect Time
1	Function-Pending Time
2	Device-Disconnect Time
3	Control-Unit-Queuing Time
4	Device-Active-Only Time
5	Device-Busy Time
6	Initial Command Response Time
7	Reserved

Each field in the EMW, when valid, contains a 32 bit binary count in which each increment of the count represents a value of 0.5 microseconds. A value of 00000000 hex represents a time period of zero seconds; the maximum value of FFFFFFFF hex represents approximately 35.79 minutes.

The accuracy of each of the measurement fields stored by the measurement facility is undefined and may vary depending on the resolution of timers implemented at the channel subsystem, the types of channels used to perform the operation, the capabili-

ties of control units accessed during the operation, and the overall length of the I/O operation that was performed. The maximum value of FFFFFFFF hex is stored if a counter overflows; the program is not alerted when an overflow occurs.

**Device-Connect Time:** Bit positions 0-31 of word 0 contain the measured device-connect time for the operation. The device-connect time is the sum of the time intervals measured whenever the device is logically connected to a channel path while the subchannel is subchannel active and the device is actively communicating with the channel path, as defined in the section “Device-Connect Time” on page 17-4.

**Function-Pending Time:** Bit positions 0-31 of word 1 contain the SSCH- or RSCH-function-pending time for the operation. Function-pending time is the time interval between acceptance of the start function (or resume function if the subchannel is in the suspended state) at the subchannel and acceptance of the first command associated with the initiation or resumption of channel-program execution at the device, as defined in the section “Function-Pending Time” on page 17-5.

**Device-Disconnect Time:** Bit positions 0-31 of word 2 contain the device-disconnect time for the operation. Device-disconnect time is the sum of the time intervals measured whenever the device is logically disconnected from the channel subsystem while the subchannel is subchannel-active, as defined in the section “Device-Disconnect Time” on page 17-5.

**Control-Unit-Queuing Time :** Bit positions 0-31 of word 3 contain the control-unit-queuing time for the operation. Control-unit-queuing time is the sum of the

time intervals measured by the control unit whenever the device is logically disconnected from the channel subsystem during an I/O operation while the device is busy with an operation initiated from a different system, as defined in the section “Control-Unit-Queuing Time” on page 17-5.

**Device-active-only time:** Bit positions 0-31 of word 4 contain the device-active-only time for the operation. Device-active-only time is the sum of the time intervals when the subchannel is device-active but not subchannel-active at the end of an I/O operation or chain of I/O operations initiated by a start function or resume function, as defined in section “Device-Active-Only Time” on page 17-6.

**Device-busy time:** Bit positions 0-31 of word 5 contain the device-busy time for the operation. Device-busy time is the sum of the time intervals when the device is found to be device busy during an attempt to initiate a start function or resume function at the subchannel, as defined in the section “Device-Busy Time” on page 17-6.

**Initial Command Response Time:** Bit positions 0-31 of word 6 contain the initial-command-response time for the operation. The initial-command-response time for an operation is the time interval beginning from when the first command of the channel program is sent to the device until the device indicates it has accepted the command.

The I/O support functions are those functions of the channel subsystem that are not directly related to the initiation or control of I/O operations. The following I/O support functions are described in this chapter:

- Channel-subsystem monitoring
- Signals and resets
- Externally initiated functions
- Status verification
- Address-limit checking
- Configuration alert
- Incorrect-length-indication suppression
- Concurrent sense
- Channel-subsystem recovery
- I/O-priority facility
- Restore-subchannel facility
- Multiple-subchannel-set facility

## Channel-Subsystem Monitoring

Monitoring facilities are provided in the channel subsystem so that the program can retrieve measured values on performance for a designated subchannel. The use of these facilities is under program control by means of the execution of the SET CHANNEL MONITOR instruction and the MODIFY SUBCHANNEL instruction.

The principal components of the channel-subsystem-monitoring facilities are the channel-subsystem-timing facility, measurement-block-update facility, and device-connect-time-measurement facility. The measurement-block-update facility and device-connect-time-measurement facility both use the channel-subsystem-timing facility but otherwise are logically distinct and operate independent of one another.

Other components of the channel-subsystem-monitoring facilities are the control-unit-queuing-measurement facility, the control-unit-defer-time facility, the device-active-only-measurement facility, the initial-command-response-measurement facility, the extended-I/O-measurement-block facility, and the extended-I/O-measurement-word facility. These enhance the measurements of the measurement-block-update facility if they are available as described in later sections, where each of the facilities that constitute the channel-subsystem-monitoring facilities is described in this chapter.

## Channel-Subsystem Timing

The channel-subsystem-timing facility provides the channel subsystem with the capability of measuring the elapsed time required for performing several different phases of the processing of a start function initiated by START SUBCHANNEL. These elapsed-time measurements are used by both the measurement-block-update facility and the device-connect-time-measurement facility to provide subchannel performance information to the program.

While every channel subsystem has a channel-subsystem-timing facility, it may or may not be provided for use with all subchannels. Subchannels for which the facility is provided have the timing-facility bit, bit 14 of word 1, stored as one in the associated subchannel-information block. (See “Timing Facility (T)” on page 15-4.) If the channel-subsystem-timing facility is not provided for the subchannel, the subchannel's timing-facility bit is stored as zero.

Subchannels that do not have the channel-subsystem-timing facility provided are those for which the characteristics of the associated device, the manner in which it is attached to the channel subsystem, or the channel-subsystem resources required to support the device are such that use of the channel-subsystem-timing facility is precluded.

The channel-subsystem-timing facility consists of at least one channel-subsystem timer and the associated logic and storage required for computing and recording the elapsed-time intervals for use by the two measurement facilities. The aspects of the channel-subsystem-timing facility that are of importance to the program are described below.

### Channel-Subsystem Timer

Each channel-subsystem timer is a binary counter that is not accessible to the program. The channel-subsystem timer provides a minimum timer resolution of 128 microseconds. A timer resolution of 1.0 microseconds is provided when FICON-I/O-interface channel paths are supported. When incrementing the channel-subsystem timer causes a carry out of the leftmost bit position, the carry is ignored, and counting continues from zero. No indications are generated as a result of the overflow.

Just as every CPU has access to a TOD clock, every channel subsystem has access to at least one channel-subsystem timer. When multiple channel-subsystem timers are provided, synchronization among these timers is also provided, creating the effect that all the timing facilities of the channel subsystem share a single timer. Synchronization among these timers may be supplied either through some TOD clock or independently by the channel subsystem.

If the TOD clocks are not synchronized, the elapsed times measured by the channel-subsystem-timing facility may have unpredictable values for some or all of the subchannels, depending on the model and on the particular channel-subsystem timer and the way the associated devices are physically attached to the system. The values are unpredictable for those devices attached to the system by separately configurable channel paths whose associated CPU TOD clocks are not synchronized.

**Synchronization:** If either the measurement-block-update mode or the device-connect-time-measurement mode is active and any of the channel-subsystem timers is found to be out of synchronization, a channel-subsystem-timer-sync check is recognized, and a channel report is generated to alert the program (see “Channel-Subsystem Recovery” on page 17-24). If neither of these modes is active, the lack of synchronization is not recognized.

## Measurement-Block Update

The measurement-block-update facility provides the program with the capability of accumulating performance information for subchannels that are enabled for the measurement-block-update mode when the measurement-block-update mode is active. A subchannel is enabled for the measurement-block-update mode by setting bit 11 of word 1 of the SCHIB operand to one and then issuing MODIFY SUB-

CHANNEL. The measurement-block-update mode is made active by the execution of SET CHANNEL MONITOR when bit 62 of general register 1 is one.

When the measurement-block-update mode is active and the subchannel is enabled for the measurement-block-update mode, information is accumulated in a measurement block associated with the subchannel. A measurement block is either a 32-byte area (format-0 measurement block) or a 64-byte area (format-1 measurement block) in main storage that is associated with a subchannel for the purpose of accumulating measurement data.

For format-0 measurement blocks, the program specifies a contiguous area of absolute storage, referred to as the measurement-block area, and subdivides this area into 32-byte blocks, one block for each subchannel for which measurement data is to be accumulated. The measurement-block-update facility uses the measurement-block index contained at the subchannel in conjunction with the measurement-block origin established by the execution of SET CHANNEL MONITOR to compute the absolute address of the measurement block associated with a subchannel.

For format-1 measurement blocks, the program provides a 64-byte contiguous area of absolute storage for the subchannel. The measurement-block-update facility uses the measurement-block address provided by the MSCH instruction to access the measurement block.

Measurement data is stored in the measurement block associated with the subchannel each time an I/O operation or chain of I/O operations initiated by a START SUBCHANNEL instruction or RESUME SUBCHANNEL instruction is suspended or is completed at the device. The completion of an I/O operation or chain of I/O operations at the device is normally determined when secondary status is accepted from the device.

The measurement data accumulated in the format-0 and format-1 measurement blocks by the measurement-block-update facility is described in the following section, "Measurement Block".

## Measurement Block

A measurement block is either a 32-byte area (format-0 measurement block) at a location designated by the program by its use of a measurement-block-

origin address in conjunction with the measurement-block index, or a 64-byte area (format-1 measurement block) at a location designated by the measurement-block address provided in the SCHIB during the execution of the MODIFY SUBCHANNEL instruction. The measurement block contains the accumulated values of the measurement data described below. When the measurement-block-update mode is active and the subchannel is enabled for measurement-block update, the measurement-block-update facility accumulates the values for the measurement data that accrue during the performance of an I/O operation or chain of I/O operations initiated by START SUBCHANNEL.

When the I/O operation or chain of I/O operations is suspended or completed and no error condition is encountered, the accrued values are added to the accumulated values in the measurement block for that subchannel. If an error condition is detected and subchannel-logout information is stored in the extended-status word (ESW), the accrued values are not added to the accumulated values in the measurement block for the subchannel, and the two count fields in the measurement block are not incremented.

If (1) any of the accrued time values is detected to exceed the internal storage provided for containing these values, (2) the control unit cannot provide an accurate queuing time or defer time for the current operation, or (3) the channel subsystem successfully recovers from certain error conditions, none of the accrued values is added to the measurement block for the subchannel, and the sample count in the measurement block is not incremented, but the SSCH+RSCH count in the block is incremented.

References to the measurement block by the measurement-block-update facility, in order to accumulate measurement data at the suspension or completion of an I/O function, are single-access references and appear to be word concurrent as observed by CPUs.

The measurement-block-update facility updates all fields in the measurement block that are required to be updated for a suspended I/O operation prior to putting the subchannel into the suspended state. The measurement-block-update facility updates all fields in the measurement block that are required to be updated for a completed I/O operation prior to making the subchannel status pending with secondary status or, if the subchannel is start pending for a subsequent operation, prior to initiating the start function.

A format-0 measurement block is stored when the measurement-block-format-control bit at the sub-channel is zero; a format-1 measurement block is stored when the measurement-block-format-control bit at the subchannel is one.

The format-0 measurement block has the following format:

Word	SSCH+RSCH Count	Sample Count
0	SSCH+RSCH Count	Sample Count
1	Device-Connect Time	
2	Function-Pending Time	
3	Device-Disconnect Time	
4	Control-Unit-Queuing Time	
5	Device-Active-Only Time	
6	Device-Busy Time	
7	Initial Command Response Time	

The format-1 measurement block has the following format:

Word	
0	SSCH+RSCH Count
1	Sample Count
2	Device-Connect Time
3	Function-Pending Time
4	Device-Disconnect Time
5	Control-Unit-Queuing Time
6	Device-Active-Only Time
7	Device-Busy Time
8	Initial Command Response Time
9	
15	Reserved

**SSCH+RSCH Count:** Bits 0-15 of word 0 in the format-0 measurement block and bits 0-31 of word 0 in the format-1 measurement block are used as a binary counter. During the performance of a start function for which measurement-block update is active, when (1) the secondary status condition is recognized or (2) the suspend function is performed,

the counter is incremented by one, and the measurement data is stored. The counter wraps around from the maximum value to 0. The program is not alerted when counter overflow occurs.

If the measurement-block-update mode is active and the subchannel is enabled for measuring, the SSCH+RSCH count is incremented even when the lack of measured values for an individual start function precludes the updating of the remaining fields of the measurement block or when the timing-facility bit for the subchannel is zero. The SSCH+RSCH count is not incremented if the measurement-block-update mode is inactive, if the subchannel is not enabled for the measurement-block update, or if subchannel-logout information has been generated for the start function.

**Sample Count:** Bits 16-31 of word 0 in the format-0 measurement block and bits 0-31 of word 1 in the format-1 measurement block are used as a binary counter. When the time-accumulation fields following word 0 of the measurement block are updated, the counter is incremented by one. On some models, certain conditions may prevent the measurement-block-update facility from obtaining the accrued values of the measurement data for an individual start function, even when the measurement-block-update mode is active and the subchannel is enabled for that mode. The control unit may also signal that it was not able to accumulate an accurate queuing time. In these situations, the sample-count field is not incremented.

The counter wraps around from the maximum value to 0. The program is not alerted when counter overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the sub-channel.

The System Library publication for the system model specifies the conditions, if any, that preclude the updating of the sample count and time-accumulation fields of the measurement block.

**Device-Connect Time:** Bit positions 0-31 of word 1 in the format-0 measurement block and bit positions 0-31 of word 2 in the format-1 measurement block contain the accumulation of measured device-connect-time intervals. The device-connect-time interval (DCTI) is the sum of the time intervals measured whenever the device is logically connected to a channel path while the subchannel is subchannel active and the device is actively communicating with the

channel path. The device-connect time does not include the intervals when a device is logically connected to a channel path but is not actively communicating with the channel. The device reports the accumulation of time intervals when the device is logically connected but not actively communicating with the channel path as control-unit-defer time. The control-unit-defer time is not included in the device-connect-time measurement but, instead, is added to the accrued device-disconnect-time measurement for the operation.

The time intervals are stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if (1) the channel-subsystem-timing facility is not provided for the subchannel, (2) the measurement-block-update mode is inactive, or (3) any of the time values accrued for the current start function has been detected to exceed the internal storage in which it was accrued.

Accumulation of device-connect-time intervals for a subchannel and storing this data in the ESW are not affected by whether the measurement-block-update mode is active. (See “Device-Connect-Time Measurement” on page 17-9.)

**Function-Pending Time:** Bit positions 0-31 of word 2 in the format-0 measurement block and bit positions 0-31 of word 3 in the format-1 measurement block contain the accumulated SSCH- and RSCH-function-pending time. Function-pending time is the time interval between acceptance of the start function (or resume function if the subchannel is in the suspended state) at the subchannel and acceptance of the first command associated with the initiation or resumption of channel-program execution at the device.

When channel-program execution is suspended because of a suspend flag in the first CCW of a channel program, the suspension occurs prior to transferring the first command to the device. In this case, the function-pending time accumulated up to that point is added to the value in the function-pending-time field of the measurement block. Function-pending time is not accrued while the subchannel is suspended. Function-pending time begins to be accrued again, in this case, when RESUME SUBCHANNEL is subsequently executed while the designated subchannel is in the suspended state.

The function-pending-time interval is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

**Device-Disconnect Time:** Bit positions 0-31 of word 3 in the format-0 measurement block and bit positions 0-31 of word 4 in the format-1 measurement block contain the accumulated device-disconnect time. Device-disconnect time is the sum of the time intervals measured whenever the device is logically disconnected from the channel subsystem while the subchannel is subchannel active. The device-disconnect time also includes the sum of control-unit-defer-time intervals reported by the device during the I/O operation.

Device-disconnect time is not accrued while the subchannel is in the suspended state. Device-disconnect time begins to be accrued again, in this case, on the first device disconnection after channel-program execution has been resumed at the device (the subchannel is again subchannel active).

The device-disconnect-time interval is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

The device-disconnect time does not include the interval between the primary status condition and the secondary status condition at the end of an I/O operation when the subchannel is no longer subchannel active but the I/O device is active. If the channel subsystem provides the device-active-only measurement facility, this time is accumulated in the device-active-only-time field of the measurement block.

**Control-Unit-Queuing Time:** Bit positions 0-31 of word 4 in the format-0 measurement block and bit positions 0-31 of word 5 in the format-1 measurement block contain the accumulated control-unit-queuing time. Control-unit-queuing time is the sum of the time intervals measured by the control unit whenever the device is logically disconnected from the channel subsystem during an I/O operation while the device is busy with an operation initiated from a different system.

Control-unit-queuing time is not accrued while the subchannel is in the suspended state. Control-unit-queuing time may be accrued for the channel program after the subchannel becomes subchannel active following a successful resumption.

The control-unit-queuing-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel or if the control unit does not provide a queuing time.

**Device-Active-Only Time:** Bit positions 0-31 of word 5 in the format-0 measurement block and bit positions 0-31 of word 6 in the format-1 measurement block contain the accumulated device-active-only time. Device-active-only time is the sum of the time intervals when the subchannel is device active but not subchannel active at the end of an I/O operation or chain of I/O operations initiated by a start function or resume function.

Device-active-only time is not accumulated when the subchannel is device active during periods when the subchannel is active; such time is accumulated as device-connect time or device-disconnect time, as appropriate.

The device-active-only-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

**Device-Busy Time:** When the extended-I/O-measurement-block facility is installed, bit positions 0-31 of word 6 in the format-0 measurement block, and bit positions 0-31 of word 7 in the format-1 measurement block contain the accumulated device-busy time. Device-busy time is the sum of the time intervals when the subchannel is device busy during an attempt to initiate a start function or resume function at the subchannel.

The device-busy-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

**Initial-Command-Response Time:** Bit positions 0-31 of word 7 in the format-0 measurement block, and bit positions 0-31 of word 8 in the format-1 measurement block contain the accumulated initial-command-response time for the subchannel. The initial-command-response time for a start or resume function is the time interval beginning from when the first command of the channel program is sent to the device until the device indicates it has accepted the command.

The initial-command-response time is stored at a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs.

This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel or if the initial-command-response-measurement facility is not installed.

**Control-Unit-Defer Time:** Control-unit-defer time is the sum of the time intervals measured by the control unit whenever the device is logically connected to the channel subsystem during an I/O operation but is not actively communicating with the channel because of device-dependent delays in channel-program execution. The control-unit-defer time is not stored in the measurement block as a separate measurement field but is used in the calculation of device-connect-time measurement and device-disconnect-time measurement for an operation.

Control-unit-defer time, if provided by a control unit, is accrued while the device is logically connected to the channel. The time is reported to the channel when channel-end status is presented that causes a device disconnection or terminates the I/O operation. Control-unit-defer time is subtracted from the device-connect-time measurement and is added to the device-disconnect-time measurement reported for the operation.

**Reserved:** The remaining words of the measurement block, along with any words associated with facilities that are not provided by the channel subsystem or the subchannel, are reserved for future use. They are not updated by the measurement-block-update facility.

**Programming Note:** It is possible for the program to fetch a portion of a measurement block immediately prior to, or during, a measurement block update by the measurement-block-update facility. To ensure

that a consistent measurement block is fetched, the program should not fetch measurement data for a subchannel during the time from when a start or resume function is initiated at the subchannel until the operation is suspended or completes with secondary status.

### **Measurement-Block Format**

The measurement block is stored as either a format-0 measurement block or a format-1 measurement block. The format-0 measurement block is a 32-byte area (format-0 measurement block) at a location designated by the program using the measurement-block origin in conjunction with the measurement-block index. The format-1 measurement block is a 64-byte area (format-1 measurement block) at a location designated by the measurement-block address provided in the SCHIB during the execution of the MODIFY SUBCHANNEL instruction. The measurement-block-format-control bit at the subchannel indicates whether a format-0 or format-1 measurement block is stored when measurement-block-update mode is active and enabled at the subchannel.

### **Measurement-Block Origin**

The measurement-block origin is the beginning of the measurement-block area in main storage, used to store format-0 measurement blocks. The absolute address of the measurement-block origin, specified on a 32-byte boundary, is passed in general register 2 to the measurement-block-update facility when SET CHANNEL MONITOR is executed with bit 62 of general register 1 set to one.

### **Measurement-Block Address**

The measurement-block address is set at the subchannel through the execution of MODIFY SUBCHANNEL. The measurement block address specifies the absolute address of the beginning of the 64-byte area to be used for accumulating format-1 measurement-block parameters for that subchannel.

**Programming Note:** The initial value of the measurement-block address is zero. The program is responsible for setting the measurement-block address to the proper value prior to enabling the subchannel for the measurement-block-update mode for format-1 measurement blocks and making the mode active.

### **Measurement-Block Key**

Bits 32-35 of general register 1 form the four-bit access key to be used for subsequent measurement-block updates when SET CHANNEL MONITOR causes the measurement-block-update mode to be made active. The measurement-block key is passed to the measurement-block-update facility whenever the measurement-block-update mode is made active. The key is used for both format-0 and format-1 measurement block updates.

### **Measurement-Block Index**

The measurement-block index is set in the subchannel through the execution of MODIFY SUBCHANNEL. The measurement-block index specifies which 32-byte measurement block, relative to the measurement-block origin, is to be used for accumulating the format-0 measurement-block parameters for that subchannel. The location of the format-0 measurement block of a subchannel is computed by the measurement-block-update facility by appending five rightmost zeros to the measurement-block index of the subchannel and adding the result to the measurement-block origin. The result is the absolute address of the 32-byte format-0 measurement block for that subchannel. When the computed measurement-block address exceeds  $2^{31}1$ , a measurement-block program-check condition is recognized, and measurement-block updating does not occur for the preceding subchannel-active period.

**Programming Note:** The initial value of the measurement-block index is zero. The program is responsible for setting the measurement-block index to the proper value prior to enabling the subchannel for the measurement-block-update mode and making the mode active. To ensure predictable results for the measured parameters in the measurement block, each subchannel for which measured parameters are to be accumulated must have a different value for its measurement-block index.

### **Measurement-Block-Update Mode**

The measurement-block-update mode is made active by the execution of SET CHANNEL MONITOR with bit 62 of general register 1 set to one. If bit 62 of general register 1 is zero when SET CHANNEL MONITOR is executed, the mode is made inactive. When the measurement-block-update mode is inactive, no measurement values are accumulated in main storage. When the measurement-block-update mode is made active, the contents of general register 2 are passed to the measurement-block-update facil-

ity as the absolute address of the measurement-block origin and is used to calculate the address of format-0 measurement blocks. The measurement-block origin is not used for format-1 measurement blocks. The MBK is also passed to the measurement-block-update facility as the access key to be used when updating either format-0 or format-1 measurement blocks for each subchannel. When the measurement-block-update mode is active, the measurement-block-update facility accumulates measurements in individual measurement blocks for subchannels whose measurement-block-update-enable bit is one. (See the section "Measurement Block" on page 17-3 for a description of the measured parameters.)

If the measurement-block-update mode is already active when SET CHANNEL MONITOR is executed, the values for the measurement-block origin and measurement-block key that are used for a subchannel enabled for measuring by the measurement-block-update facility are dependent upon whether SET CHANNEL MONITOR is executed prior to, during, or subsequent to the execution of START SUBCHANNEL for that subchannel. If SET CHANNEL MONITOR is executed prior to START SUBCHANNEL, the current measurement-block origin and measurement-block key are in control. If SET CHANNEL MONITOR is executed during or subsequent to execution of START SUBCHANNEL, it is unpredictable whether the measurement-block origin and measurement-block key that are in control are old or current.

### **Measurement-Block-Format Control**

Bit 29, word 6, of the SCHIB is the measurement-block-format-control bit. This bit provides the capability of specifying whether a format-0 or format-1 measurement block is stored on a subchannel basis. The initial value of the bit is zero. When MODIFY SUBCHANNEL is executed with the measurement-block-format-control bit in the SCHIB operand set to one, the format-1 measurement block is specified for the subchannel. If the measurement-block-update mode is active and enabled at the subchannel, the measurement-block-update facility stores a format-1 measurement-block for the subchannel, starting with the next START SUBCHANNEL issued to that subchannel. Similarly, if MODIFY SUBCHANNEL is executed with measurement-block-format-control bit of the SCHIB operand set to zero by the program, the measurement-block-update facility stores a format-0 measurement-block for the subchannel, starting with

the next START SUBCHANNEL issued to that subchannel.

### **Measurement-Block-Update Enable**

Bit 11 of word 1 of the SCHIB is the measurement-block-update-enable bit. This bit provides the capability of controlling the accumulation of measurement-block parameters on a subchannel basis. The initial value of the enable bit is zero. When MODIFY SUBCHANNEL is executed with the enable bit set to one in the SCHIB, the subchannel is enabled for the measurement-block-update mode. If the measurement-block-update mode is active, the measurement-block-update facility accumulates measurement-block parameters for the subchannel, starting with the next START SUBCHANNEL issued to that subchannel. Conversely, if MODIFY SUBCHANNEL is executed with bit 11 of word 1 of the SCHIB operand set to zero by the program, the subchannel is disabled for the measurement-block-update mode, and no additional measurement-block parameters are accumulated for that subchannel.

### **Control-Unit-Queuing Measurement**

The control-unit-queuing-measurement facility allows the channel subsystem to accept queuing times from control units and, in conjunction with the measurement-block-update facility, to accumulate those times in the measurement block.

The System Library publication for the control-unit model specifies its ability to supply queuing time. If a control-unit model is capable of supplying queuing time, the publication specifies the conditions that prevent the control unit from accumulating an accurate control-unit-queuing time.

### **Control-Unit-Defer Time**

The control-unit-defer-time facility allows the channel subsystem to accept defer times from control units and, in conjunction with the measurement-block-update facility, to modify the device-connect and device-disconnect times reported in the measurement block to reflect the defer time. The control-unit-defer time is subtracted from the device-connect-time measurement and is added to the device-disconnect-time measurement reported for an I/O operation.

The System Library publication for the control-unit model specifies its ability to supply defer time. If a control-unit model is capable of supplying defer time, the publication specifies the conditions that prevent

the control unit from accumulating an accurate control-unit-defer time.

### **Device-Active-Only Measurement**

The device-active-only-measurement facility permits the channel subsystem to report the times that the device is disconnected between primary status and secondary status at the end of an I/O operation or chain of I/O operations.

The measurement-block updates are performed at the time that secondary status is accepted from the I/O device, in order that the device-active time between primary status and secondary status can be reported.

If the subchannel is start pending when secondary status is accepted from the I/O device and the measurement-block update is to be performed, the measurement-block update is performed prior to performing the start function. If measurement-block errors occur, they are reported to the program along with the secondary status instead of performing the start function.

### **Initial-Command-Response Measurement**

The initial-command-response-measurement facility allows the channel subsystem to calculate initial-command-response time for I/O operations and, in conjunction with the measurement-block-update facility, to accumulate those times in the measurement block. The initial-command-response time is accumulated in word 7 of the measurement block.

### **Time-Interval-Measurement Accuracy**

On some models, when time intervals are to be measured and condition code 0 is set for START SUBCHANNEL (or RESUME SUBCHANNEL in the case of a suspended subchannel), a period of latency may occur prior to the initiation of the function-pending time measurement. The System Library publication for the system model specifies the mean latency value and variance for each of the measured time intervals.

#### **Programming Notes:**

1. Excessive delays may be encountered by the channel subsystem when attempting to update measurement data if the program is concurrently accessing the same measurement-block area. A programming convention should ensure that the

storage block designated by SET CHANNEL MONITOR is made read-only while the measurement-block-update mode is active.

2. To ensure that programs written to support measurement functions are executed properly, the program should initialize all the measurement blocks to zeros prior to making the measurement-block-update mode active. Only zeros should appear in the reserved and unused words of the measurement blocks.
3. When the incrementing of an accumulated value causes a carry to be propagated out of bit position 0, the carry is ignored, and accumulating continues from zero on.

### **Device-Connect-Time Measurement**

The device-connect-time-measurement facility provides the program with the capability of retrieving the length of time that a device is actively communicating with the channel subsystem while executing a channel program. The measured length of time that the device spends actively communicating on a channel path during the execution of a channel program is called the device-connect-time interval (DCTI). Control-unit-defer time is not included in the DCTI.

If timing facilities are provided for the subchannel, the DCTI value is passed to the program in the extended-status word (ESW) at the completion of the operation when the primary-status condition is cleared by TEST SUBCHANNEL and when TEST SUBCHANNEL clears an intermediate-status condition alone while the subchannel is suspended. The DCTI value passed in the ESW pertains to the previous subchannel-active period. The passing of the DCTI in the ESW is under program control by the SET CHANNEL MONITOR device-connect-time-measurement mode-control bit and the corresponding enable bit in the subchannel. However, the DCTI value is not stored in the ESW if the I/O function initiated by START SUBCHANNEL is terminated because of an error condition that is described by subchannel logout. See the section “Extended-Status Format 0” on page 16-33. In this case, the extended-status bit (L) of the SCSW is stored as one, indicating that the ESW contains logout information describing the error condition. See the section “Extended-Status Word” on page 16-33 for the description of the logout information. If the accrued DCTI value exceeded 8.388608 seconds

during the previous subchannel-active period, then the maximum value (FFFF hex) is passed in the ESW.

## Device-Connect-Time-Measurement Mode

The device-connect-time-measurement mode is made active by the execution of SET CHANNEL MONITOR when bit 63 of general register 1 is one. If bit 63 of general register 1 is zero when SET CHANNEL MONITOR is executed, the mode is made inactive, and DCTIs are not passed to the program. When timing facilities are provided for the subchannel, the device-connect-time-measurement mode is active, and the subchannel is enabled for the mode, the DCTI value is passed to the program in the ESW stored when TEST SUBCHANNEL (1) clears the primary-interruption condition with no logout information indicated in the SCSW (extended-status-word-format bit is zero) or (2) clears the intermediate-status condition alone while the subchannel is suspended.

If a start function is currently being executed with a subchannel enabled for the device-connect-time-measurement mode when SET CHANNEL MONITOR makes this mode active for the channel subsystem, the value of the DCTI stored under the appropriate conditions may be zero, a partial result, or the full and correct value, depending on the model and the progress of the start function at the time the mode was activated.

Provision of the DCTI value in the measurement-block area is not affected by whether the device-connect-time-measurement mode is active.

## Device-Connect-Time-Measurement Enable

Bit 12 of word 1 of the SCHIB is the device-connect-time measurement-mode-enable bit. This bit provides the program with the capability of selectively controlling the storing of DCTI values for a subchannel when the device-connect-time-measurement mode is active. The initial value of the enable bit is zero. When this enable bit is one in the SCHIB and MODIFY SUBCHANNEL is executed, the subchannel is enabled for the device-connect-time-measurement mode. If the device-connect-time-measurement mode is active, the device-connect-time-measurement facility begins providing DCTI values for the subchannel, starting with the next START SUBCHANNEL issued to the subchannel. In this situation, the DCTI values are provided in the ESW (see

the section “Extended-Status Format 2” on page 16-40). Similarly, if MODIFY SUBCHANNEL is executed with bit 12 of word 1 of the SCHIB operand set to zero by the program, the subchannel is disabled for the device-connect-time-measurement mode, and no further DCTI values are passed to the program for that subchannel.

## Extended Measurement Word

The extended-I/O-measurement-word facility provides the program with the capability of retrieving measurement information for a channel program. The measurement information is stored into the extended-measurement word (EMW) in the Interruption Response Block when the extended-measurement-word enable bit is one at the subchannel. See the section “Extended-Measurement Word” on page 16-42 in Chapter 16, “I/O Interruptions,” for the description of the extended-measurement word.

When the extended-measurement-word is enabled for the subchannel, measurement values are passed to program in the EMW when TEST SUBCHANNEL clears a primary-status condition, secondary-status condition alone, or an intermediate-status condition alone while the subchannel is suspended. The measurement values stored in the EMW pertain to the previous subchannel-active and device-active period. Measurement values are not stored in the EMW if the I/O function initiated by START SUBCHANNEL is terminated because of an error condition that is described by subchannel logout (see the section “Extended-Status Format 0” on page 16-33). In this case, the extended-status bit (L) of the SCSW is stored as one, indicating that the ESW contains logout information describing the error condition. See the section “Extended-Status Word” on page 16-33, for the description of the logout information. If any of the accrued measurement values exceeded the maximum value capable of being measured during the previous subchannel-active and device-active period, then the maximum value is stored for that value in the EMW.

## Extended-Measurement-Word Enable

Bit 30 of word 6 of the SCHIB is the extended-measurement-word enable bit. This bit provides the program with the capability of selectively controlling the storing of measurement values for a subchannel. The initial value of the enable bit is zero. When this enable bit is one in the SCHIB and MODIFY SUBCHANNEL is executed, the subchannel is enabled

for the extended-measurement-word and the extended-measurement-word facility begins providing measurement values for the subchannel starting with the next START SUBCHANNEL issued to the subchannel. Similarly, if MODIFY SUBCHANNEL is executed with bit 30, word 6, of the SCHIB operand set to zero by the program, the subchannel is disabled for the extended-measurement-word and no further measurement values are passed to the program for that subchannel.

---

## Signals and Resets

During system operation, it may become necessary to terminate an I/O operation or to reset either the I/O system or a portion of the I/O system. (The I/O system consists of the channel subsystem plus all of the attached control units and devices.) Various signals and resets are provided for this purpose. Three signals are provided for the channel subsystem to notify an I/O device to terminate an operation or perform a reset function or both. Two resets are provided to cause the channel subsystem to reinitialize certain information contained either at the I/O device or at the channel subsystem.

## Signals

The request that the channel subsystem initiate a signaling sequence is made by one of the following:

1. The program's issuance of the CLEAR SUBCHANNEL, HALT SUBCHANNEL, or RESET CHANNEL PATH instruction
2. The I/O device's signaling of I/O-error alert
3. The channel subsystem itself, upon detecting certain error conditions or equipment malfunctions

The three signals are the halt signal, the clear signal, and the reset signal.

### Halt Signal

The halt signal is provided so the channel subsystem can terminate an I/O operation. The halt signal is issued by the channel subsystem as part of the halt function performed subsequent to the execution of HALT SUBCHANNEL. The halt signal is also issued

by the channel subsystem when certain error conditions are encountered.

For the parallel-I/O-interface type of channel path, the halt signal results in the channel subsystem using the interface-disconnect sequence control defined in the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974.

For the ESCON-I/O-interface type of channel path, the halt signal results in the channel subsystem using the cancel function defined in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

For the FICON-I/O-interface type of channel path, the halt signal results in the channel subsystem using the cancel function defined in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*.

### Clear Signal

The clear signal is provided so the channel subsystem can terminate an I/O operation and reset status and control information contained at the device. The clear signal is issued as part of the clear function performed subsequent to the execution of CLEAR SUBCHANNEL. The clear signal is also issued by the channel subsystem when certain error conditions or equipment malfunctions are detected by the I/O device or the channel subsystem.

For the parallel-I/O-interface type of channel path, the clear signal results in the channel subsystem using the selective-reset sequence control defined in the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974.

For the ESCON-I/O-interface type of channel path, the clear signal results in the channel subsystem using the selective-reset function defined in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

For the FICON-I/O-interface type of channel path, the clear signal results in the channel subsystem using the selective-reset function defined in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*.

If an I/O operation is in progress at the device and the device is actively communicating over a channel path in the performance of that I/O operation when a clear signal is received on that channel path, the device disconnects from that channel path upon receiving the clear signal. Data transfer and any operation using the facilities of the control unit are immediately concluded, and the I/O device is not necessarily positioned at the beginning of a block. Mechanical motion not involving the use of the control unit, such as rewinding magnetic tape or positioning a disk-access mechanism, proceeds to the normal stopping point, if possible. The device may appear busy until termination of the mechanical motion or the inherent cycle of operation, if any, whereupon it becomes available. Status information in the device and control unit is reset, but an interruption condition may be generated upon the completion of any mechanical operation.

## Reset Signal

The reset signal is provided so the channel subsystem can reset all I/O devices on a channel path. The reset signal is issued by the channel subsystem as part of the channel-path-reset function performed subsequent to the execution of RESET CHANNEL PATH. The reset signal is also issued by the channel subsystem as part of the I/O-system-reset function.

For the parallel-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset sequence control defined in the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974.

For the ESCON-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset function defined in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

For the FICON-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset function defined in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*.

## Resets

Two resets are provided so the channel subsystem can reinitialize certain information contained at either the I/O device or the channel subsystem. The

request that the channel subsystem initiate one of the reset functions is made by one of the following:

1. The program's issuance of the RESET CHANNEL PATH instruction
2. The operator's activation of a system-reset-clear or system-reset-normal key or a load-clear or load-normal key
3. The channel subsystem itself upon detecting certain error conditions or equipment malfunctions

The resets are channel-path reset and I/O-system reset.

### Channel-Path Reset

The channel-path-reset facility provides a mechanism to reset certain indications that pertain to a designated channel path at all associated subchannels. Channel-path reset occurs when the channel subsystem performs the channel-path-reset function initiated by RESET CHANNEL PATH. (See "RESET CHANNEL PATH" on page 14-9.) All internal indications of dedicated allegiance, control unit busy, and device busy that pertain to the designated channel path are cleared in all subchannels, and reset is signaled on that channel path.

The receipt of the reset signal by control units attached to that channel path causes all operations in progress and all status, mode settings, and allegiance, pertaining to that channel path, of the control unit and its attached devices to be reset. (See also the description of the system-reset-signal actions in "I/O-System Reset" on page 17-12.)

The results of the channel-path-reset function on the designated channel path are communicated to the program by means of a subsequent machine-check-interruption condition generated by the channel subsystem (see "Channel-Subsystem Recovery" on page 17-24).

### I/O-System Reset

The I/O-system-reset function is performed when the channel subsystem is powered on, when initial program loading is initiated manually (see "Initial Program Loading" on page 17-16), and when the system-reset-clear or system-reset-normal key is activated. The I/O-system-reset function cannot be initiated under program control; it must be initiated manually. I/O-system reset may fail to complete due to malfunctions detected at the channel subsystem

or on a channel path. I/O-system reset is performed as part of subsystem reset, which also resets all floating interruption requests, including pending I/O interruptions. (See “Subsystem Reset” on page 4-53.) Detailed descriptions of the effects of I/O-system reset on the various components of the I/O system appear later in this chapter.

I/O-system reset provides a means for placing the channel subsystem and its attached I/O devices in the initialized state. I/O-system reset affects only the channel-subsystem configuration in which it is performed, including all channel-subsystem components configured to that channel subsystem. I/O-system reset has no effect on any system components that are not part of the channel-subsystem configuration that is being reset. The effects of I/O-system reset on the configured components of the channel subsystem are described in the following sections.

**Channel-Subsystem State:** I/O-system reset causes the channel subsystem to be placed in the initialized state, with all the channel-subsystem components in the states described in the following sections. All operations in progress are terminated and reset, and all indications of prior conditions are reset. These indications include status information, interruption conditions (but not pending interruptions), dedicated-allegiance conditions, pending channel reports, and all internal information regarding prior conditions and operations. In the initialized state, the channel subsystem has no activity in progress and is ready to perform the initial-program-loading (IPL) function or respond to I/O instructions, as described in “I/O Instructions” on page 14-1.

**Control Units and Devices:** I/O-system reset causes a reset signal to be sent on all configured channel paths, including those which are not physically available (as indicated by the PAM bit being zero) because of a permanent error condition detected earlier. When the reset signal is received by a control unit, control-unit functions in progress, control-unit status, control-unit allegiance, and control-unit modes for the resetting channel path are reset. Device operations in progress, device status, device allegiance, and the device mode for the resetting channel path are also reset. Control-unit and device mode, allegiance, status, and I/O functions in progress for other channel paths are not affected.

For devices that are operating in the single-path mode, an operation can be in progress for, at most,

one channel path. Therefore, if the reset signal is received on that channel path, the operation in progress is reset. Devices that have the dynamic-reconnection feature and are operating in the multipath mode, however, have the capability to establish an allegiance to a group of channel paths during an I/O operation, where all the channel paths of the path group are configured to the same channel subsystem. If an operation is in progress for a device that is operating in the multipath mode and the reset signal is received on one of the channel paths of that path group, then the operation in progress is reset for the resetting channel path only. Although the operation in progress cannot continue on the resetting channel path, it can continue on the other channel paths of the path group, subject to the following restrictions:

1. If the device is actively communicating with the channel subsystem on a channel path when it receives the reset signal on that channel path, then the operation is reset unconditionally, regardless of path groups.
2. If the operation is in progress in the multipath mode but the path group consists only of the resetting path, then the operation is reset.
3. Except as noted in item 2, if the operation in progress is currently in a disconnected state (device not actively communicating with the channel subsystem) or is active on another channel path of a path group, system reset has no effect upon the continued performance of the operation.

A control unit is completely reset after the reset signal has been received on all its channel paths, provided no new activity is initiated at the control unit between the receipt of the first and last reset signal. “Completely reset” means that the current operation, if any, at the control unit is terminated and that control-unit allegiance, control-unit status, and the control-unit mode, if any, are reset.

An I/O device is completely reset after the reset signal has been received on all channel paths of all control units by which the device is accessible, provided no new activity is initiated at the device between the receipt of the first and last reset signal. “Completely reset” means that the current operation, if any, at the device is terminated and that device allegiance, device status, and the device mode are reset.

In summary, system reset always causes an operation in progress to be reset for the channel path on which the reset signal is received. If the resetting channel path is the only channel path for which the operation is in progress, then the operation is completely reset. If a device is actively communicating on a channel path over which the reset signal is received, then the operation in progress is unconditionally and completely reset.

The reset signal is not received by control units and devices on channel paths from which the control unit has been partitioned. A control unit is partitioned from a channel path by means of an enable/disable switch on the control unit for each channel path by which it is accessible. Multi-tagged, unsolicited status, if any, remains pending at the control unit for such a channel path in this case. However, from the point of view of the program, the control unit and device appear to be completely reset if the reset signal is received by the control unit on all the channel paths by which it is currently accessible.

The resultant reset state of individual control units and devices is described in the System Library publication for the control unit.

**Channel Paths:** I/O-system reset causes a reset signal to be sent on all configured channel paths and causes the channel subsystem to be placed in the reset and initialized state, as described in the previous sections. As a result of these actions, all communication between the channel subsystem and its attached control units and devices is terminated and the components reset, and all configured channel paths are made quiescent or are deconfigured.

**Subchannels:** I/O-system reset causes all operations on all subchannels to be concluded. Status information, all interruption conditions (but not pending interruptions), dedicated-allegiance conditions, and internal indications regarding prior conditions and operations in all subchannels are reset, and all valid subchannels are placed in the initialized state.

In the initialized state, the subchannel parameters of all valid subchannels are set to their initial values. The initial values of the following subchannel parameters are zeros:

- Interruption parameter
- I/O-interruption-subclass code (ISC)
- Enabled
- Limit mode

- Measurement mode
- Multipath mode
- Path-not-operational mask
- Last-path-used mask
- Measurement-block index
- Concurrent sense

The initial values of the following subchannel parameters are assigned as part of the installation procedure for the device associated with each valid subchannel:

- Timing facility
- Device number
- Logical-path mask (same value as path-installed mask)
- Path-installed mask
- Path-available mask
- Channel-path ID 0-7

The values assigned may depend upon the particular system model and the configuration; dependencies, if any, are described in the System Library publication for the system model. Programming considerations may further constrain the values assigned.

The initial value of the path-operational mask is all ones.

The device-number-valid bit is one for all subchannels having an assigned I/O device.

The initial value of the model-dependent area of the subchannel-information block is described in the System Library publication for the system model.

The initial value of the subchannel-status word and extended-status word is all zeros.

The initialized state of the subchannel is the state specified by the initial values for the subchannel parameters described above. The description of the subchannel parameters can be found in “Subchannel-Information Block” on page 15-1, “Subchannel-Status Word” on page 16-6, and “Extended-Status Word” on page 16-33.

**Channel-Path-Reset Facility:** I/O-system reset causes the channel-path-reset facility to be reset. A channel-path-reset function initiated by RESET CHANNEL PATH, either pending or in progress, is overridden by I/O-system reset. The machine-check-interruption condition, which normally signals the completion of a channel-path-reset function, is not

generated for a channel-path-reset function that is pending or in progress at the time I/O-system reset occurs.

**Address-Limit-Checking Facility:** I/O-system reset causes the address-limit-checking facility to be reset. The address-limit value is initialized to all zeros and validated.

**Channel-Subsystem-Monitoring Facilities:** I/O-system reset causes the channel-subsystem-monitoring facilities to be reset. The measurement-block-update mode and the device-connect-time-measurement mode, if active, are made inactive. The measurement-block origin and the measurement-block key are both initialized to zeros and validated.

**Pending Channel Reports:** I/O-system reset causes pending channel reports to be reset.

**Channel-Subsystem Timer:** I/O-system reset does not necessarily affect the contents of the channel-subsystem timer. In models that provide channel-subsystem-timer checking, I/O-system reset may cause the channel-subsystem timer to be validated.

**Pending I/O Interruptions:** I/O-system reset does not affect pending I/O interruptions. However, during subsystem reset, I/O interruptions are cleared concurrently with the performance of I/O-system reset. (See “Subsystem Reset” on page 4-53.)

Area Affected	Effect on I/O-System Reset <sup>1</sup>
Channel-subsystem state	Reset and initialized
Control units and devices	Reset
Channel paths	Quiescent
Subchannels	Reset and initialized
Interruption parameter	Zeros <sup>2</sup>
I/O-interruption-subclass code (ISC)	Zeros <sup>2</sup>
Enabled bit	Zero <sup>2</sup>
Address-limit-mode bits	Zeros <sup>2</sup>
Timing-facility bit	Installed value <sup>2</sup>
Multipath-mode bit	Zero <sup>2</sup>
Measurement-mode bits	Zeros <sup>2</sup>
Device-number-valid bit	Installed value <sup>2</sup>
Device number	Installed value <sup>2</sup>
Logical-path mask	Equal to path-installed mask value <sup>2</sup>
Path-not-operational mask	Zeros <sup>2</sup>
Last-path-used mask	Zeros <sup>2</sup>
Path-installed mask	Installed value <sup>2</sup>
Measurement-block index	Zeros <sup>2</sup>
Path-operational mask	Ones <sup>2</sup>
Path-available mask	Installed value <sup>2,3</sup>
Channel-path ID 0-7	Installed value <sup>2</sup>
Concurrent-sense bit	Zero <sup>2</sup>
Subchannel-status word	Zeros <sup>2</sup>
Extended-status word	Zeros <sup>2</sup>
Model-dependent area	Model dependent <sup>2</sup>
Channel-path-reset facility	Reset
Address-limit-checking facility	Reset and initialized
Address-limit value	Zeros <sup>2</sup>
Channel-subsystem-monitoring facility	Reset and initialized
Measurement-block-update mode	Inactive <sup>2</sup>
Device-connect-time-measurement mode	Inactive <sup>2</sup>
Measurement-block origin	Zeros <sup>2</sup>
Measurement-block key	Zeros <sup>2</sup>
Pending channel-report words	Cleared
Channel-subsystem timer	Unchanged/validated
<b>Explanation:</b>	
1 For a detailed description of the effect of I/O-system reset on each area, see the text.	
2 Initialized value.	
3 Also subject to model-dependent configuration controls, if any.	

Figure 17-1. Summary of I/O-System-Reset Actions

## Externally Initiated Functions

I/O-system reset, which is an externally initiated function, is described in “I/O-System Reset” on page 17-12.

## Initial Program Loading

Initial program loading (IPL) provides a manual means for causing a program to be read from a designated device and for initiating the execution of that program.

Some models may provide additional controls and indications relating to IPL; this additional information is specified in the System Library publication for the model.

There are two types of IPL: CCW-type IPL and list-directed IPL. CCW-type IPL is provided by all machine configurations. List-directed IPL may be provided, depending on the model.

### CCW-type IPL

CCW-type IPL is initiated manually by setting the load-unit-address controls to a four-digit number to designate an input device and by subsequently activating the load-clear or load-normal key.

Activating the load-clear or load-normal key sets the architectural mode to the ESA/390 mode. For ease of reference, the additional elements of the description of ESA/390 IPL are given below.

Activating the load-clear key causes a clear reset to be performed on the configuration.

Activating the load-normal key causes an initial CPU reset to be performed on this CPU, CPU reset to be propagated to all other CPUs in the configuration, and a subsystem reset to be performed on the remainder of the configuration.

In the loading part of the operation, after the resets have been performed, this CPU enters the load state. This CPU does not necessarily enter the stopped state during performance of the reset. The load indicator is on while the CPU is in the load state.

Subsequently, if conditions allow, a read operation is initiated from the designated input device and associated subchannel. The read operation is performed as if a START SUBCHANNEL instruction were executed that designated (1) the subchannel corresponding to the device number specified by the load-unit-address controls and (2) an ORB containing all zeros, except for a byte of all ones in the logical-path-mask field. The ORB parameters are interpreted by the channel subsystem as follows:

- **Interruption parameter:** All zeros
- **Subchannel key:** All zeros
- **Suspend control:** Zero (suspension not allowed)
- **CCW format:** Zero
- **CCW prefetch:** Zero (prefetching not allowed)

- **Initial-status-interruption control:** Zero (no request)
- **Address-limit-checking control:** Zero (no checking)
- **Suppress suspended interruption:** Zero (suppression not allowed)
- **Logical-path mask:** Ones (all channel paths logically available)
- **Incorrect-length-suppression mode:** Zero (ignored because format-0 CCWs are specified)
- **Channel-program address:** Absolute address 0

The first CCW to be executed is not fetched from storage. Instead, the effect is as if an implied format-0 CCW, beginning in absolute location 0 and having the following detailed format, were executed:

**Loc.**

0	0 0 0 0 0 1 0	0 0
4	0 1 1 0 0 0 0 0	/ / / / / / 0 0 0 0 0 0 0 0 0 0 1 1 0 0 0

0                   8                   16                   31

In the illustration above, the CCW specifies a read command with the modifier bits zeros, a data address of 0, a byte count of 24, the chain-command flag one, the suppress-incorrect-length-indication flag one, the chain-data flag zero, the skip flag zero, the program-controlled-interruption (PCI) flag zero, the indirect-data-address (IDA) flag zero, and the suspend flag zero. The CCW fetched, as a result of command chaining, from location 8 or 16, as well as any subsequent CCW in the IPL sequence, is interpreted the same as a CCW in any I/O operation, except that any PCI flags that are specified in the IPL channel program are ignored.

At the time the subchannel is made start pending for the IPL read, it is also enabled, which ensures proper handling of subsequent status from the device by the channel subsystem and facilitates subsequent I/O operations using the IPL device. (Except for the subchannel used by the IPL I/O operation, each subchannel must first be made enabled by MODIFY SUBCHANNEL before it can accept a start function or any status from the device.)

When the IPL subchannel becomes status pending for the last operation of the IPL channel program, no I/O-interruption condition is generated. Instead, the subsystem ID is stored in absolute locations 184-187, zeros are stored in absolute locations 188-191, and the subchannel is cleared of the pending status as if TEST SUBCHANNEL had been exe-

cuted but without storing information usually stored in an IRB. If the subchannel-status field that would normally have been stored is all zeros and the device-status field that would normally have been stored contains only the channel-end indication, with or without the device-end indication, the IPL I/O operation is considered to be completed successfully. If the device-end status for the IPL I/O operation is provided separately after channel-end status, it causes an I/O-interruption condition to be generated.

If an interface-control check is detected during execution of the IPL channel program, some models may re-initiate the same channel program on another channel path. The other path chosen is any logically-available channel path to the designated device on which the IPL channel program has not previously been initiated during the current IPL operation. (See programming note 6 on page 17-19 for additional information.)

When the IPL I/O operation is completed successfully, a new PSW is loaded from absolute locations 0-7. If the PSW loading is successful and no malfunctions are recognized that preclude the completion of IPL, then the CPU leaves the load state, and the load indicator is turned off. If the rate control is set to the process position, the CPU enters the operating state, and CPU operation proceeds under control of the new PSW. If the rate control is set to the instruction-step position, the CPU enters the stopped state, with the manual indicator on, after the new PSW has been loaded.

If the IPL I/O operation or the PSW loading is not completed successfully, the CPU remains in the load state, and the load indicator remains on.

IPL does not complete when any of the following occurs

- No subchannel contains a valid device number equal to the IPL device number specified by the load-unit-address controls.
- A malfunction is detected in the CPU, main storage, or channel subsystem that precludes the completion of IPL.
- Unsolicited alert status is presented by the device subsequent to the subchannel becoming start pending for the IPL read and before the IPL subchannel becomes subchannel active. The IPL read operation is not initiated in this case.

- There were no available channel paths to the IPL device.
- On every available channel path to the IPL device, either the IPL device appeared not operational or an interface-control check was detected.
- The IPL device presented a status byte containing indications other than channel end, device end, status modifier, control unit end, control unit busy, device busy, or retry status during the IPL I/O operation. Whenever control unit end, control unit busy, or device busy is presented in the status byte, normal path-management actions are taken.
- A subchannel-status indication other than PCI was generated during the IPL I/O operation, except that on some models, detection of an interface-control check may cause the I/O operation to be retried on another available channel path to the IPL device.
- The PSW loaded from absolute locations 0-7 has a PSW-format error of the type that is recognized early.

Except in the cases of no corresponding subchannel for the device number entered or a machine malfunction, the subsystem ID of the IPL device is stored in absolute locations 184-187; otherwise, the contents of these locations are unpredictable. In all cases of unsuccessful IPL, the contents of absolute locations 0-7 are unpredictable.

Subsequent to a successful IPL, the subchannel parameters contain the normal values as if an actual START SUBCHANNEL had been executed, designating the ORB as described above.

#### **Programming Notes:**

1. The information read and placed at absolute locations 8-15 and 16-23 may be used as CCWs for reading additional information during the IPL I/O operation: the CCW at location 8 may specify reading additional CCWs elsewhere in storage, and the CCW at location 16 may specify the transfer-in-channel command, causing transfer to these CCWs.
2. The status-modifier bit has its normal effect during the IPL I/O operation, causing the channel subsystem to fetch and chain to the CCW whose

address is 16 higher than that of the current CCW. This applies also to the initial chaining that occurs after completion of the read operation specified by the implicit CCW.

3. The PSW that is loaded at the completion of the IPL operation may be provided by the first eight bytes of the IPL I/O operation or may be placed at absolute locations 0-7 by a subsequent CCW.
4. Activating the load-normal key implicitly specifies the use of the first 24 bytes of main storage and the eight bytes at absolute locations 184-191. Since the remainder of the IPL program may be placed in any part of storage, it is possible to preserve such areas of storage as may be helpful in debugging or recovery. The IPL program should not be placed in the low 512 bytes of storage since that area is reserved as described in a programming note under "Compatibility between z/Architecture and ESA/390" on page 1-22. When the load-clear key is activated, the IPL program starts with a cleared machine in a known state, except that information on external storage remains unchanged.
5. When the PSW at absolute location 0 has bit 14 set to one, the CPU is placed in the wait state after the IPL operation is completed. At that point, the load and manual indicators are off, and the wait indicator is on.
6. When the program receives control after the machine leaves the load state during IPL, the last-path-used mask (LPUM) in the subchannel-information block (SCHIB) for the IPL device should be saved. The program should use this saved LPUM as the logical-path mask (LPM) in the ORB until the program reaches the point in its initialization where it has the ability to process and recover from interface-control checks, and verify that all of the channel paths associated with the subchannel are connected to the same device.

When multiple paths are associated with the subchannel of the IPL device, it is possible that miscabling of one or more of the paths can cause the program initialization to proceed on different devices. This affects the integrity of the IPL process. The program should ensure that all paths are connected to the same device, but this typically is not possible before program initialization completes. Thus the use of the saved LPUM ensures that all I/O operations to the IPL device

during program initialization are executed on the same device, allowing postponement of the checking of the paths.

Using the saved LPUM also helps to ensure that the channel subsystem will not select a path on which errors would prevent completion of the program initialization, since the path indicated in the LPUM has demonstrated its functionality. On some models, using the saved LPUM also ensures that the path selection will not re-select a path on which an interface-control check was detected while the machine was in the load state.

## List-Directed IPL

List-directed IPL supports the use of I/O devices which are not accessed by CCWs. List-directed IPL may be provided for a logical partition or virtual machine, depending on the model and the amount of memory available to the logical partition or virtual machine. The terms logical partition and virtual machine are not defined in this publication. The term logical partition is defined in the System Library publications. The term virtual machine is defined in the virtual-machine product manuals.

List-directed IPL is initiated by activating the load-clear-list-directed or load-with-dump key. Prior to activating either of these keys, the list-directed-IPL parameters are entered using a model-dependent console. List-directed-IPL parameters include the following information:

- Information which identifies the I/O device from which a program is to be loaded. This I/O device is referred to as the load device.
- Information which identifies a location on a load device from which a program will be loaded.
- Information to be used by the program which will be loaded from the load device.

The list-directed-IPL parameters required by a specific machine and the means by which they are entered are specified in the System Library publications.

After the list-directed-IPL parameters have been entered, the load-clear-list-directed or load-with-dump key for a particular CPU is activated. In the description which follows, the term "this CPU" refers to the CPU in the configuration for which the load-clear-list-directed key was activated.

Activating the load-clear-list-directed key causes a clear reset to be performed on all of the CPUs in the configuration.

Activating the load-with-dump key causes a store-status operation to be performed on this CPU. After the store-status operation, an initial-CPU-reset operation is performed on this CPU, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration.

In the loading part of the operation, after the resets have been performed, the operations listed below are performed.

- If the rate control is not in the process position, it is forced into the process position.
- If the list-directed IPL operation was initiated by activating the load-with-dump key, the contents of a model-dependent number of contiguous logical-partition or virtual-machine storage locations starting with absolute location 0 are stored in a model-dependent holding area. The data stored includes the contents of all storage locations into which the program will be loaded from the load device. See Programming Note 4 for additional information.
- The program to be loaded from the load device is loaded into logical-partition or virtual-machine storage at the locations specified on the load device.
- A system IPL-parameter block used by the machine during list-directed IPL is placed in storage in the format shown in Figure 17-2 on page 17-20. The absolute address of the first byte of the system IPL-parameter block is stored in absolute address locations 20-23. An XML document containing the system IPL parameters immediately follows the last byte of the system IPL-parameter block. (See “Extensible Markup Language (XML) 1.0,” available from “World Wide Web Consortium”([www.w3c.org](http://www.w3c.org)) for information regarding XML.)

The system IPL-parameter block has the following format:

Word	Length
0	
1	System IPL Parameters
n	

31

Figure 17-2. System IPL-Parameter Block

Bits 0-31 of word 0 of the system IPL-parameter block contains a length field. The length field contains a 32-bit binary number representing the number of bytes occupied by the system IPL-parameter block. Words 1 through n contain the system IPL parameters.

If no errors occur during the operations listed above, then if a subchannel is associated with the IPL-device, the subsystem-identification word is stored in absolute locations 184-187; otherwise zeroes are stored in absolute locations 184-187. Additionally, zeroes are stored in absolute locations 188-191, and a new PSW is loaded from absolute locations 0-7. If the PSW loading is successful and if no malfunctions are recognized which preclude execution of the program which was loaded from the load device, then operation proceeds under control of the new PSW.

If errors occur during the operations listed above, or if the PSW loading is not successful, then this CPU remains in the operating state. See the appropriate System Library publications for additional information.

When list-directed IPL was initiated by activating the load-clear-list-directed key, the state of the machine resources at the time when the loaded program is initiated is the same as it was immediately after the clear reset was performed except as indicated below. For a description of the state of the machine resources immediately after the clear reset was performed, see “Resets” on page 4-49.

- This CPU is in the operating state. The contents of the ALB and TLB for this CPU are unpredictable.
- The PSW for this CPU is set to the contents of absolute storage locations 0-7.

- Main storage locations into which the program was loaded from the load device contain the program which was loaded, except for absolute storage locations 20-23 and 184-191. Absolute storage locations 20-23 contain the absolute address of the system IPL-parameter block; storage locations starting with this absolute address contain the system IPL-parameter block, immediately followed by an XML document containing the same system IPL parameters. If a subchannel is associated with the IPL device, then absolute storage locations 184-187 contain the subsystem-identification word for the IPL-device and absolute storage locations 188-191 contain zeroes; otherwise, absolute storage locations 184-191 contain zeroes. The contents of all other storage locations are unpredictable.
- The ACC and F bits of the storage keys associated with all main storage locations are set to zero. The R and C bits of the storage keys associated with the first 4 K-byte block of storage, the blocks of storage containing the XML document and IPL-parameter list, and the blocks of storage containing the loaded program are set to one. The R and C bits of the storage keys associated with all other blocks of storage are unpredictable.
- The TOD clock is unaffected by initial-program loading.

When list-directed IPL was initiated by activating the load-with-dump key, the state of the machine resources when control is passed to the loaded program is as follows:

- The I/O system has been reset.
- The state of all CPUs in the configuration except for this CPU is the same as it was immediately after the CPUs were reset.
- This CPU is in the operating state. The contents of all registers, the ALB, and the TLB for this CPU are unpredictable.
- The PSW for this CPU is set to the contents of absolute storage locations 0-7.
- The contents of all main storage locations which were not stored in the model-dependent holding area are unchanged from the time when the load-with-dump key was activated.

- The contents of all main storage locations which were stored in the model-dependent holding area are unpredictable except as follows:
  - Main storage locations into which the program was loaded from the load device contain the program which was loaded, except for absolute storage locations 20-23.
  - Absolute storage locations 20-23 contain the absolute address of the system IPL-parameter block; storage locations starting with the absolute address indicated by the contents of absolute addresses 20-23 contain the system IPL-parameter block, which is immediately followed by an XML document containing the system IPL parameters.
  - If a subchannel is associated with the IPL device, then absolute storage locations 184-187 contain the subsystem-identification word for the IPL-device and absolute storage locations 188-191 contain zeroes; otherwise, absolute storage locations 184-191 contain zeroes.
- The storage keys associated with the blocks of main storage which were stored in the model-dependent holding area are unpredictable. The storage keys associated with all other blocks of main storage are in the same state as they were immediately after the CPUs were reset.
- The TOD clock is unaffected by initial-program loading.

List-directed IPL does not complete if any of the following occurs:

- A malfunction is detected in the CPU, channel subsystem, or main storage which precludes the completion of IPL.
- The list-directed IPL parameters did not contain sufficient information to identify the load device or the program on the load device.
- An I/O device designated by the list-directed-IPL parameters is not in the machine configuration.
- The I/O device designated by the list-directed-IPL parameters is a CCW-type device and is not supported by list-directed IPL.
- The I/O device appeared not operational.

- The amount of storage in the logical partition or virtual machine is insufficient to allow list-directed IPL to complete.
- The PSW to be loaded from locations 0-7 has a PSW-format error of the type that is recognized early.

#### **Programming Notes:**

1. The executable portion of the program loaded during list-directed IPL should be located in absolute storage starting at absolute storage locations 8192 and higher. This is necessary in order to avoid use of the architecturally assigned storage locations. See “Assigned Storage Locations” on page 3-58.
2. When the address indicated by storage locations 20-23 is above 16 MB, it is necessary for the machine to be in 31-bit addressing mode in order to access the IPL-parameter list and XML document.
3. When list-directed IPL is initiated by activation of the load-clear-list-directed key, the program loaded from the load device is typically an operating-system loader. In this case, the load device may also contain the operating system to be loaded by the operating-system loader. See the applicable operating-system manuals for additional information.
4. When list-directed IPL is initiated by activation of the load-with-dump key, the contents of storage which are affected by the IPL operation are stored in a model-dependent holding area so that they can be retrieved by the program which was loaded from the load device. The program loaded from the load device is typically an O/S-specific system dump program which stores the retrieved data onto a dump device. This process ensures that the contents of storage affected by the IPL operation are preserved for analysis during subsequent debug operations. See the applicable operating system manuals for additional information.

## **Reconfiguration of the I/O System**

Reconfiguration of the I/O system is handled in a model-dependent manner. For example, changes may be made under program control, by using the model-dependent DIAGNOSE instruction; or manu-

ally, by using system-operator configuration controls; or by using a combination of DIAGNOSE and manual controls. The method used depends on the system model. The System Library publication for the system model specifies how the changes are made. The partitioning of channel paths because of reconfiguration is indicated by the setting of the PAM bits in the SCHIB stored when STORE SUBCHANNEL is executed (see “Path-Available Mask (PAM)” on page 15-7).

---

## **Status Verification**

The status-verification facility provides the channel subsystem with a means of indicating that a device has presented a device-status byte that has valid CBC but that contained a combination of bits that was inappropriate when the status byte was presented to the channel subsystem. The indication provided to the program in the ESW by the channel subsystem is called device-status check. When the channel subsystem recognizes a device-status-check condition, an interface-control-check condition is also recognized. For a summary of the status combinations considered to be appropriate or inappropriate, see the System Library publications *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202, and *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974, and the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*.

---

## **Address-Limit Checking**

The address-limit-checking facility provides a storage-protection mechanism for I/O data accesses to storage that augments key-controlled protection. When address-limit checking is used, absolute storage is divided into two parts by a program-controlled address-limit value. I/O data accesses can then be optionally restricted to only one of the two parts of absolute storage by the limit mode at each subchannel. The address-limit constraint applies at a higher priority than key-controlled protection, that is, I/O data accesses to the part of main storage that is protected by address-limit checking are prevented even when the subchannel key is zero or matches the key in storage. Address-limit checking does not apply to the fetching of CCWs, IDAWs and MIDAWs.

The address-limit-checking facility consists of the following elements:

- The I/O instruction SET ADDRESS LIMIT.
- The limit mode at each subchannel.
- The address-limit-checking-control bit in the ORB.

The execution of SET ADDRESS LIMIT passes the contents of general register 1 to the address-limit-checking facility to be used as the address-limit value. Bits 32 and 48-63 of general register 1 must be zeros to designate a valid absolute address on a 64K-byte boundary; otherwise, an operand exception is recognized, and the execution of the instruction is suppressed.

The limit mode at each subchannel indicates the manner in which address-limit checking is to be performed. The limit mode is set by placing the desired value in bit positions 9 and 10 of word 1 in the SCHIB and executing MODIFY SUBCHANNEL. The settings of these bits in the SCHIB have the following meanings:

- 00 No limit checking (initialized value).
- 01 Data address must be equal to or greater than the current address limit.
- 10 Data address must be less than the current address limit.
- 11 Reserved. This combination of limit-mode bits causes an operand exception to be recognized when MODIFY SUBCHANNEL is executed.

The address-limit-checking-control bit, bit 11 of word 1 of the ORB, specifies whether address-limit checking is to be used for the start function that is accepted when the execution of START SUBCHANNEL causes the contents of the ORB to be passed to the subchannel. If the address-limit-checking-control bit is zero when the contents of the ORB are passed, address-limit checking is not specified for that start function. If the bit is one, address-limit checking is specified and is under the control of the current address limit and the current setting of the limit mode at the subchannel.

During the performance of the start function, an attempt to access an absolute storage location for

data that is protected by an address limit (either high or low) is recognized as an address-limit violation, and the access is not allowed. A program-check condition is recognized, and channel-program execution is terminated, just as when an attempt is made to access an invalid address.

---

## Configuration Alert

The configuration-alert facility provides a detection mechanism for devices that are not associated with a subchannel in the configuration. The configuration-alert facility notifies the program, by means of a channel report, that a device which is not associated with a subchannel has attempted to communicate with the program.

Each device must be assigned to a subchannel during an installation procedure; otherwise, the channel subsystem is unable to generate an I/O-interruption condition for the device. This is because the I/O-interruption code contains the subchannel number that identifies the particular device causing the I/O-interruption condition. When a device that is not associated with a subchannel attempts to communicate with the channel subsystem, the configuration-alert facility generates a channel report in which the unassociated device is identified. For a description of the means by which the program is notified of a pending channel report and how the information in the channel report is retrieved, see "Channel Report" on page 17-24.

---

## Incorrect-Length-Indication Suppression

The incorrect-length-indication-suppression facility allows the indication of incorrect length for immediate operations to be suppressed in the same manner when using format-1 CCWs as when using format-0 CCWs. When the incorrect-length-indication-suppression facility is installed, bit 24 of word 1 of the ORB specifies whether the channel subsystem is to suppress the indication of incorrect length for an immediate operation when format-1 CCWs are used or whether this indication will remain under the control of the SLI flag of the current CCW (as is the case for CCWs not executed as immediate operations). This bit provides the capability for a channel program

to operate in the same manner regarding the indication of incorrect length regardless of whether format-0 or format-1 CCWs are used.

---

## Concurrent Sense

The concurrent-sense facility provides a mechanism whereby sense information that is provided by the device can be presented by the channel subsystem to the program in the same IRB that contains the unit-check indication when the subchannel is in the concurrent-sense mode. The concurrent-sense mode is made active at a subchannel for which the concurrent-sense facility is applicable when MODIFY SUBCHANNEL is executed and bit 31 of word 6 of the SCHIB operand is set to one. The concurrent-sense facility is applicable to subchannels that are associated with channel paths by which the channel subsystem can attempt to retrieve sense information from the device without requiring program intervention.

---

## Channel-Subsystem Recovery

The channel subsystem provides various methods for extensive detection of malfunctions and other conditions to ensure the integrity of channel-subsystem operation and to achieve automatic recovery of some malfunctions.

The method used to report a particular malfunction or other condition is dependent upon the severity of the malfunction or other condition and the degree to which the malfunction or other condition can be isolated. A malfunction or other condition in the channel subsystem may be indicated to the program by information being stored by one of the following methods:

1. Information is provided in the IRB describing a condition that has been recognized by either the channel subsystem or device that must be brought to the attention of the program. Generally, this information is made available to the program by the execution of TEST SUBCHANNEL, which is usually executed in response to the occurrence of an I/O interruption. (See "Interruption Action" on page 16-5, for a definition of the information stored, as well as "Interruptions" on page 6-1.)

2. Information is provided in a channel report describing a machine malfunction affecting the identified facility associated with the channel-subsystem. This information is made available to the program by the execution of STORE CHANNEL REPORT WORD, which is usually executed in response to the occurrence of a machine-check interruption. (See "Machine-Check Handling" on page 11-1 for a description of the machine-check-interruption mechanism and the contents of the machine-check-interruption code.)
3. Information is provided in a channel report describing a malfunction or other condition affecting a collection of channel-subsystem facilities. This information is made available to the program as indicated in item 2.
4. Information is provided in the machine-check-interruption code (MCIC) describing a malfunction affecting the continued operational integrity of the channel subsystem. (See "Channel-Subsystem Damage" on page 11-17.)
5. Information is provided in the MCIC describing a malfunction affecting the continued operational integrity of a process or of the system. (See "Instruction-Processing Damage" on page 11-15 and "System Damage" on page 11-14.)

Channel reports are used to report malfunctions or other conditions only when the use of the I/O-interruption facility is not appropriate and in preference to reporting channel-subsystem damage, instruction-processing damage, or system damage.

## Channel Report

When a malfunction or other condition affecting elements of the channel subsystem has been recognized, a channel report is generated. The performance of recovery actions by the program or by external means may be required to gain recovery from the error condition. The channel report indicates the source of the channel report and the recovery state to the extent necessary for determining the proper recovery action. A channel report consists of one or more channel-report words (CRWs) that have been generated from an analysis of the malfunction or other condition. The inclusion of two or more CRWs within a channel report is indicated by the chaining flag being stored as one in all of the CRWs of the channel report except the last one in the chain.

When a channel report is made pending by the channel subsystem for retrieval and analysis by the program (by means of the execution of STORE CHANNEL REPORT WORD), a malfunction or other condition that affects the normal operation of one or more of the channel-subsystem facilities has been recognized. If the channel report that is made pending is an initial channel report, a machine-check-interruption condition is generated that indicates one or more CRWs are pending at the channel subsystem. A channel report is initial either if it is the first channel report to be generated after the most recent I/O-system reset or if no previously generated reports are pending and the last STORE CHANNEL REPORT WORD instruction that was executed resulted in the setting of condition code 1, indicating that no channel report was pending. When the machine-check interruption occurs and bit 9 of the machine-check-interruption code (channel report pending) is one, a channel report is pending. If the program clears the first CRW of a channel report before the associated machine-check interruption has occurred, some models may reset the machine-check-interruption condition, and the associated machine-check interruption does not occur. A machine-check interruption indicating that a channel report is pending occurs only if the machine-check mask (PSW bit 13) and the channel-report-pending subclass mask, bit 3 of control register 14, are both ones.

If the channel report that is made pending is not an initial channel report, a machine-check-interruption condition is not generated. The CRW that is presented to the program in response to the first STORE CHANNEL REPORT WORD instruction that is executed after a machine-check interruption may or may not be part of the initial channel report that caused the machine-check condition to be generated. A pending channel-report word is cleared by any CPU executing STORE CHANNEL REPORT WORD, regardless of whether a machine-check interruption has occurred in any CPU. If a CRW is not pending and STORE CHANNEL REPORT WORD is executed, condition code 1 is set, and zeros are stored at the location designated by the second-operand address. During the execution of STORE CHANNEL REPORT WORD as a result of receiving a machine-check interruption, condition code 1 may be set, and zeros may be stored because (1) the related channel report has been cleared by another CPU or (2) a malfunction occurred during the generation of a channel report. In the latter case, if, during a subsequent attempt, a valid channel report can be made

pending, an additional machine-check-interruption condition is generated.

When a channel report consists of multiple chained CRWs, they are presented to the program in the same order that they are placed in the chain by the channel subsystem as a result of consecutive executions of STORE CHANNEL REPORT WORD. If, for example, the first CRW of a chain is presented to the program as a result of executing STORE CHANNEL REPORT WORD, the CRW that is presented as a result of the next execution of STORE CHANNEL REPORT WORD is the second CRW of the same chain and not a CRW that is part of another channel report.

Channel reports are not presented to the program in any special order, except for channel reports whose first or only CRW indicates the same reporting-source code and the same reporting-source ID. These channel reports are presented to the program in the same order that they are generated by the channel subsystem, but they are not necessarily presented consecutively. For example, suppose the channel subsystem generates channel reports A, B, and C, in that order. The first CRW of channel reports B and C indicates the same reporting-source code and the same reporting-source ID. Channel report B is presented to the program before channel report C is presented, but channel report A may be presented after channel report B and before channel report C.

#### **Programming Notes:**

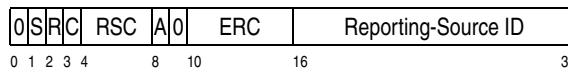

1. The information that is provided in a single CRW may be made obsolete by another CRW that is subsequently generated for the same channel-subsystem facility. Therefore, the information that is provided in one channel report should be interpreted in light of the information provided by all of the channel reports that are pending at a given instant.
2. A machine-check-interruption condition is not always generated when a channel report is made pending. The conditions that result in a machine-check-interruption condition being generated are described earlier in this section.
3. After a machine-check interruption has occurred with bit 9 of the machine-check-interruption code set to one, STORE CHANNEL REPORT WORD should be issued repeatedly until all of the pend-

- ing channel reports have been cleared and condition code 1 has been set.
4. A CRW-overflow condition can occur if the program does not issue successive STORE CHANNEL REPORT WORD instructions in a timely manner after the machine-check interruption occurs.
  5. The number of CRWs that can be pending at the same time is model dependent. During the existence of an overflow condition, CRWs that would have otherwise been made pending are lost and are never presented to the program.

## Channel-Report Word

The channel-report word (CRW) provides information to the program that can be used to facilitate the recovery of an I/O operation, a device, or some element of the channel subsystem, such as a channel path or subchannel.

The format of the CRW is as follows:

**Solicited CRW (S):** Bit 1, when one, indicates a solicited CRW. A CRW is considered by the channel subsystem to be solicited if it is made pending as the direct result of some action that is taken by the program. When bit 1 is zero, the CRW is unsolicited and has been made pending as the result of an action taken by the channel subsystem that is independent of the program.

**Overflow (R):** Bit 2, when one, indicates that a CRW-overflow condition has been recognized since this CRW became pending and that one or more CRWs have been lost. This bit is one in the CRW that has most recently been set pending when the overflow condition is recognized. When bit 2 is zero, a CRW-overflow condition has not been recognized.

A CRW that is part of a channel report is not made pending, even though the overflow condition does not exist, if an overflow condition prevented a previous CRW of that report from being made pending.

**Chaining (C):** Bit 3, when one, and when the overflow flag is zero, indicates chaining of associated CRWs. Chaining of CRWs is indicated whenever a

malfunction or other condition is described by more than a single CRW. The chaining flag is zero if the channel report is described by a single CRW or if the CRW is the last CRW of a channel report.

The chaining flag is not meaningful if the overflow bit, bit 2, is one.

**Reporting-Source Code (RSC):** Bits 4-7 identify the channel-subsystem facility that is associated with the channel report. Some facilities are further identified in the reporting-source-identification field (see below). The following combinations of bits identify the facilities:

Bits				
4	5	6	7	Facility
0	0	1	0	Monitoring facility
0	0	1	1	Subchannel
0	1	0	0	Channel Path
1	0	0	1	Configuration-alert facility
1	0	1	1	Channel subsystem

All other bit combinations in the reporting-source-code field are reserved.

**Ancillary Report (A):** Bit 8, when one, indicates that a malfunction of a system component has occurred that was recognized previously or which has affected the activity of multiple channel-subsystem facilities. When the malfunction affects the activity of multiple channel-subsystem facilities, an ancillary-report condition is recognized for all of the affected facilities except one. This bit, when zero, indicates that this malfunction of a system component was not recognized previously. This bit is meaningful for all channel reports.

Depending on the model, recognition of an ancillary-report condition may not be provided, or it may not be provided for all system malfunctions that affect channel-subsystem facilities. When ancillary-report recognition is not provided, bit 8 is set to zero.

**Error-Recovery Code (ERC):** Bits 10-15, when zero, indicate that the channel subsystem has error information regarding the channel-subsystem facility identified in the reporting-source code, and that the program can now request that information. Otherwise, bit positions 10-15 contain the error-recovery code that defines the recovery state of the channel-subsystem facility identified in the reporting-source

code. This field, when used in conjunction with the reporting-source code, can be used by the program to determine whether the identified facility has already been recovered and is available for use or whether recovery actions are still required. The following error-recovery codes are defined:

Bits						
10	11	12	13	14	15	State
0	0	0	0	0	0	Event-information pending
0	0	0	0	0	1	Available
0	0	0	0	1	0	Initialized
0	0	0	0	1	1	Temporary error
0	0	0	1	0	0	Installed parameters initialized
0	0	0	1	0	1	Terminal
0	0	0	1	1	0	Permanent error with facility not initialized
0	0	0	1	1	1	Permanent error with facility initialized
0	0	1	0	0	0	Installed parameters modified
0	0	1	0	1	0	Installed parameters restored <sup>1</sup>

**Explanation:**

- 1. Installed-parameters restored is presented only if reporting of the installed-parameters-restored CRW is enabled in the restore-subchannel facility.

All other bit combinations in the error-recovery-code field are reserved.

The specific meaning of each error-recovery code depends on the particular reporting-source code that accompanies it in a CRW. The error-recovery codes are defined as follows:

**Event-Information Pending:** Event information for the identified facility is available for retrieval by the program. This CRW does not indicate the state of the identified facility.

**Available:** The identified facility is in the same state that the program would expect if the CRW had not been generated.

**Initialized:** The identified facility is in the same state that existed immediately following the I/O-system reset that was part of the most recent system IPL.

**Temporary Error:** The identified facility is not operating in a normal manner or has recognized the occurrence of an abnormal event. It is expected that subsequent actions either will restore the facility to

normal operation or will record the appropriate information describing the abnormal event.

**Installed Parameters Initialized:** This state is the same as the initialized state, except that one or more parameters that are associated with the facility and that are not modifiable by the program may have been changed.

On some models that do not implement the restore-subchannel facility, or in the absence of enablement by the program of reporting of the installed-parameters-restored CRW by the restore-subchannel facility, the installed-parameters-initialized CRW may be reported as a result of the channel subsystem's recovery of the facility designated by the reporting-source ID.

**Terminal:** The identified facility is in a state such that an operation that was in progress can neither be completed nor terminated in the normal manner.

**Permanent Error with Facility Not Initialized:** The identified facility is in a state of malfunction, and the channel subsystem has not caused a reset function to be performed for that facility.

**Permanent Error with Facility Initialized:** The identified facility is in a state of malfunction, and the channel subsystem has caused or may have caused a reset function to be performed for that facility.

**Installed Parameters Modified:** One or more parameters of the specified facility have been changed.

**Installed Parameters Restored:** This state is the same as the initialized state, except that one or more parameters that are associated with the facility and that are not modifiable by the program may have been changed from their most recent values back to their initialized values a result of the channel subsystem's recovery of the facility.

**Reporting-Source ID (RSID):** Bit positions 16-31 contain the reporting-source ID, which may, depending upon the condition that caused the channel report and the reporting-source code, either further identify the affected channel-subsystem facility or provide additional information describing the condition that caused the channel report. The RSID field has the

following format as a function of the bit settings of the reporting-source code.

Reporting-Source				Reporting-Source ID			
4	5	6	7	Bits 16-31			
0	0	1	0	0000	0000	0000	0000
0	0	1	1	xxxx	xxxx	xxxx	xxxx
0	0	1	1	0000	0000	00ss	0000
0	1	0	0	0000	0000	yyyy	yyyy
1	0	0	1	0000	0000	yyyy	yyyy
1	0	1	1	0000	0000	0000	0000

**Note:**

**xxxx xxxx xxxx xxxx** Subchannel Number

**ss** Subchan-set ID when the MSS facility is installed and the CRW is chained immediately following a CRW for a subchannel.

**yyyy yyyy** Channel-path ID (CHPID)

When the MSS facility is installed an additional CRW is chained to every channel report for subchannels. The content of this chained CRW is identical to the original CRW except for the RSID field. In this chained CRW, bit positions 10-11 of the RSID field contain the SSID identifying the subchannel set.

## Restore-Subchannel Facility

The restore-subchannel facility may be available on a model implementing z/Architecture. This facility provides the means for the channel subsystem to recover a damaged subchannel and report the recovery to the program by means of a CRW. When the facility is installed and reporting of the installed-parameters-restored CRW is enabled in the restore-subchannel facility, the channel subsystem may recover the damaged subchannel and make a CRW pending that indicates installed-parameters restored. When the facility is installed and reporting of the installed-parameters-restored CRW is not enabled, the channel subsystem may recover the damaged subchannel and make a CRW pending that indicates installed-parameters initialized.

In some models that do not implement the restore-subchannel facility, the channel subsystem may nevertheless recover a damaged subchannel, and make a CRW pending that indicates installed-parameters initialized.

## Extended-Subchannel-Logout Facility

When the extended-subchannel-logout facility is installed and enabled, all fibre-channel (FC) channel paths can create extended-subchannel logouts, under applicable error conditions, and generate I/O interruptions that indicate such a logout is pending retrieval. The extended-subchannel logouts are stored in and retrieved from a model-dependent number of extended-subchannel-logout buffers associated with each channel path supported by the facility.

When TEST SUBCHANNEL for a subchannel that specifies an FC channel path stores an interruption-response block (IRB) containing a format-0 ESW in which the extended-subchannel-logout-pending (E) bit is 1, an extended-subchannel logout is pending for the specified subchannel. Words 2-3 of the format-0 ESW contain the extended-subchannel-logout descriptor (ESLD) that identifies the logout and the channel path for which the logout is pending.

If all of the buffers for a given channel contain pending extended-subchannel logouts, the logouts will remain pending for a model-dependent time interval. If, during that time interval, a subsequent condition occurs that warrants a new extended-subchannel logout, that logout is not made and is lost. If the time interval has been exceeded and the program has not used the ESLD to retrieve a pending logout, the logout may be removed from the buffer or the buffer may be reused to contain a subsequent logout. When a logout is removed from a buffer and the buffer is not reused, the ESLD is no longer recognized as a valid logout identifier. When a buffer is reused, the ESLD may be recognized as a valid logout identifier albeit for a logout different from the logout for which the original I/O interruption was generated.

## Channel-Subsystem-I/O-Priority Facility

The channel-subsystem-I/O-priority facility provides a means by which the program can establish a priority relationship, at the channel subsystem, among the subchannels that are placed into the start-pending state when START SUBCHANNEL is executed and

condition code 0 is indicated. For I/O-subchannels that are configured to fibre-channel channel paths (FICON and FICON-converted channel paths), it also provides a means by which the program can establish a priority relationship for I/O operations at the fibre-channel-attached control units.

The program assigns the desired channel-subsystem priority and control-unit priority by specifying the desired priority numbers in the ORB extension when START SUBCHANNEL is executed.

The channel-subsystem-priority number specified in the ORB is used by the channel subsystem to determine the order in which start-pending and resume-pending subchannels are selected when the channel subsystem attempts to initiate a start function or a resume function. See the section “Start Function and Resume Function” on page 15-18 for details about these functions. In general, I/O subchannels that are in the start-pending or resume-pending state and have a higher priority number are selected for start-function or resume-function initiation by the channel subsystem before start-pending or resume-pending subchannels that have a lower priority number. The specific priority selection algorithm used by the channel subsystem for this purpose depends on the model. Additionally, the channel subsystem also applies a fairness selection algorithm in conjunction with the priority selection algorithm when selecting I/O subchannels. The specific fairness selection algorithm also depends on the model. For all models, the channel-subsystem priority and fairness selection algorithms are always applied to I/O subchannels that are either start pending or resume pending. Some models may also apply both algorithms to subchannels that are either clear pending or halt pending. See a model’s System-Library publication for a description of the priority and fairness selection algorithms that the model provides and whether these algorithms are also applied to clear-pending or halt-pending subchannels.

The control-unit-priority number specified in the ORB is used by control units attached to fibre-channel channel paths in order to determine the priority of the execution of CCWs at the control unit. See “Control-Unit (CU) Priority.” on page 15-25 for additional information.

## Number of Channel-Subsystem-Priority Levels

Depending on the model, fewer than 256 channel-subsystem-priority levels may be provided by the channel subsystem. Each priority level that the model provides is designated by an eight-bit unsigned binary integer. The lowest provided channel-subsystem-priority level is designated by the integer 0, and each succeeding higher priority level is designated by the next-higher sequential integer. For example, if the model provides 16 priority levels, they are numbered 0-15, respectively, from the lowest priority level to the highest priority level.

---

## Multiple-Subchannel-Set Facility

The multiple-subchannel-set (MSS) facility increases the maximum number of subchannels that can be configured to a program. When the MSS facility is not provided, a single set of subchannels, in the range 0-65,535 may be provided for a program. When the MSS facility is provided, a maximum of four sets of subchannels may be provided for a program. Each subchannel set provides from one to 64K subchannels in the range 0 to 65,535. A two-bit unsigned binary integer, in the range of 0-3, called the sub-channel-set identifier (SSID) is used to specify each provided subchannel set. The default subchannel set for a program is SSID 0. The initialized state of the MSS facility is disabled, in this state the MSS facility functions are not provided to programs executing in logical partitions.

When the MSS facility is provided, a subchannel is specified by a unique address formed by the concatenation of:

1. The subchannel-set identifier (SSID) of the sub-channel-image set to which the designated sub-channel-image is configured,
2. The subchannel number of the subchannel-image being accessed.

## HFP Arithmetic

### HFP Number Representation

A hexadecimal-floating-point (HFP) number consists of a sign bit, a hexadecimal fraction, and an unsigned seven-bit binary integer called the characteristic. The characteristic represents a signed exponent and is obtained by adding 64 to the exponent value (excess-64 notation). The range of the characteristic is 0 to 127, which corresponds to an exponent range of -64 to +63. The magnitude of an HFP number is the product of its fraction and the number 16 raised to the power of the exponent that is represented by its characteristic. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

The fraction of an HFP number is treated as a hexadecimal number because it is considered to be multiplied by a number which is a power of 16. The name, fraction, indicates that the radix point is assumed to be immediately to the left of the leftmost fraction digit.

When an HFP operation would cause the result exponent to exceed 63, the characteristic wraps around from 127 to 0, and an HFP-exponent-overflow condition exists. The result characteristic is then too small by 128. When an operation would cause the exponent to be less than -64, the characteristic

wraps around from 0 to 127, and an HFP-exponent-underflow condition exists. The result characteristic is then too large by 128, except that a zero characteristic is produced when a true zero is forced.

A true zero is an HFP number with a zero characteristic and zero fraction. A true zero may arise as the normal result of an arithmetic operation because of the particular magnitude of the operands. For HFP operations, the result is forced to be a positive true zero when:

1. An HFP exponent underflow occurs and the HFP-exponent-underflow mask bit in the PSW is zero.
2. The result fraction of an addition or subtraction operation is zero and the HFP-significance mask bit in the PSW is zero.
3. The operand of the CONVERT FROM FIXED instruction is zero.
4. The dividend in the DIVIDE instruction has a zero fraction.
5. The operand of the HALVE, LOAD FP INTEGER, or SQUARE ROOT instruction has a zero fraction.
6. One or both operands of a multiplication operation has a zero fraction.

Instruction	Nonzero Result Normalized	Zero Result Forced to True Zero		Zero Result Made Positive	
		Short and Long	Extended	Short and Long	Extended
ADD NORMALIZED	Yes	Y/N	Y/N	Yes	Yes
ADD UNNORMALIZED	No	Y/N	—	Yes	—

SUBTRACT NORMALIZED	Yes	Y/N	Y/N	Yes	Yes
SUBTRACT UNNORMALIZED	No	Y/N	—	Yes	—

**Explanation:**

- Not applicable.
- <sup>1</sup> Floating-point-support instruction.

Y/N When the HFP-significance mask bit (PSW bit 23) is zero, a true zero is forced. When the HFP-significance mask bit is one, the characteristic remains unchanged, and a program interruption for HFP significance occurs.

Figure 18-1. Normalization and Zero Handling for Instructions with HFP Results

Item 2, above, applies to normalized and unnormalized instructions.

When a program interruption for HFP exponent underflow occurs, a true zero is not forced; instead, the fraction and sign remain correct, and the characteristic is too large by 128. When a program interruption for HFP significance occurs, the fraction remains zero, the sign is positive, and the characteristic remains correct.

The sign of a sum, difference, product, quotient, square root, the result of CONVERT FROM FIXED, or the result of LOAD FP INTEGER with a zero fraction is positive. The sign for a zero fraction resulting from other HFP operations is established from the operand sign, the same as for nonzero fractions.

## Normalization

A quantity can be represented with the greatest precision by an HFP number of a given fraction length

when that number is normalized. A normalized HFP number has a nonzero leftmost hexadecimal fraction digit. If one or more leftmost fraction digits are zeros, the number is said to be unnormalized.

Unnormalized numbers are normalized by shifting the fraction left, one digit at a time, until the leftmost hexadecimal digit is nonzero and reducing the characteristic by the number of hexadecimal digits shifted. A number with a zero fraction cannot be normalized; either its characteristic remains unchanged or its characteristic is made zero when the result is forced to be a true zero.

Addition and subtraction with extended operands, as well as the MULTIPLY, DIVIDE, CONVERT FROM FIXED, HALVE, LOAD FP INTEGER, and SQUARE ROOT operations, are performed only with normalization. Addition and subtraction with short or long operands may be specified as either normalized or unnormalized. For all other operations, the result is produced without normalization.

With unnormalized operations, leftmost zeros in the result fraction are not eliminated. The result may or may not be in normalized form, depending upon the original operands.

In both normalized and unnormalized operations, the initial operands need not be in normalized form. The operands for multiply, divide, and square-root operations are normalized before the arithmetic process. For other normalized operations, normalization takes place when the intermediate arithmetic result is changed to the final result.

When the intermediate result of addition, subtraction, or rounding causes the fraction to overflow, the fraction is shifted right by one hexadecimal-digit position, and the value one is supplied to the vacated leftmost digit position. The fraction is then truncated to the final result length, while the characteristic is increased by one. This adjustment is made for both normalized and unnormalized operations.

Figure 18-1 on page 18-2 summarizes, for all instructions producing HFP results, the handling of zero results and whether normalization occurs for nonzero results.

**Programming Note:** Up to three leftmost bits of the fraction of a normalized number may be zeros, since the nonzero test applies to the entire leftmost hexadecimal digit.

## HFP Data Formats

HFP numbers have a 32-bit (short) format, a 64-bit (long) format, or a 128-bit (extended) format. Numbers in the short and long formats may be designated as operands both in storage and in the floating-point registers, whereas operands having the extended format can be designated only in the floating-point registers.

In all formats, the first bit (bit 0) is the sign bit (S). The next seven bits are the characteristic. In the short and long formats, the remaining bits constitute the fraction, which consists of six or 14 hexadecimal digits, respectively.

### HFP Short Format

S	Characteristic	6-Digit Fraction	
0 1	8		31

### HFP Long Format

S	Characteristic	14-Digit Fraction	
0 1	8		31
14-Digit Fraction (continued)			
32			63

### HFP Extended Format

S	High-Order Characteristic	Leftmost 14 Digits of 28-Digit Fraction	
0 1	8		31
Leftmost 14 Digits of 28-Digit Fraction (continued)			
32			63
S	Low-Order Characteristic	Rightmost 14 Digits of 28-Digit Fraction	
64 65	72		95
Rightmost 14 Digits of 28-Digit Fraction (continued)			
96			127

An extended HFP number has a 28-digit fraction and consists of two long HFP numbers that are called the high-order and low-order parts. The high-order part may be any long HFP number. The fraction of the high-order part contains the leftmost 14 hexadecimal digits of the 28-digit fraction. The characteristic and sign of the high-order part are the characteristic and sign of the extended HFP number. If the high-order part is normalized, the extended number is considered normalized. The fraction of the low-order part

contains the rightmost 14 digits of the 28-digit fraction. The sign and characteristic of the low-order part of an extended operand are ignored.

When a result is generated in the extended format and placed in a register pair, the sign of the low-order part is made the same as that of the high-order part, and, unless the result is a true zero, the low-order characteristic is made 14 less than the high-order characteristic. When the subtraction of 14 would cause the low-order characteristic to become less than zero, the characteristic is made 128 greater than its correct value. (Thus, the subtraction is performed modulo 128.) HFP exponent underflow is indicated only when the high-order characteristic underflows.

When an extended result is made a true zero, both the high-order and low-order parts are made a true zero.

The range covered by the magnitude (M) of a normalized HFP number depends on the format.

In the short format:

$$16^{-65} \leq M \leq (1 - 16^{-6}) \times 16^{63}$$

In the long format:

$$16^{-65} \leq M \leq (1 - 16^{-14}) \times 16^{63}$$

In the extended format:

$$16^{-65} \leq M \leq (1 - 16^{-28}) \times 16^{63}$$

In all formats, approximately:

$$5.4 \times 10^{-79} \leq M \leq 7.2 \times 10^{75}$$

Although the final result of an HFP operation has six hexadecimal fraction digits in the short format, 14 fraction digits in the long format, and 28 fraction digits in the extended format, intermediate results have one additional hexadecimal digit on the right. This digit is called the guard digit. The guard digit may increase the precision of the final result because it participates in addition, subtraction, and comparison operations and in the left shift that occurs during normalization.

The entire set of HFP operations with normalized results is available for short, long, and extended operands in register-register versions; and for short and long operands in register-storage versions. Most instructions generate a result that has the same format as the source operands, except that there are multiplication operations which can generate a long product from short operands or an extended product

from long operands. Other exceptions are instructions which convert operands from one floating-point format to another or between floating-point and fixed-point (binary-integer) formats.

### Programming Notes:

1. In the absence of an HFP exponent overflow or HFP exponent underflow, the long HFP number constituting the low-order part of an extended result correctly expresses the value of the low-order part of the extended result when the characteristic of the high-order part is 14 or higher. This applies also when the result is a true zero. When the high-order characteristic is less than 14 but the number is not a true zero, the low-order part, when considered as a long HFP number, does not express the correct characteristic value.
2. The entire fraction of an extended result participates in normalization. The low-order part alone may or may not appear to be a normalized long HFP number, depending on whether the 15th digit of the normalized 28-digit fraction is nonzero or zero.

---

## Instructions

The HFP instructions and their mnemonics and operation codes are listed in Figure 18-2 on page 18-5. The figure indicates, in the column labeled "Characteristics", the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All HFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. The AFP-register-control bit must be one when an AFP register is specified as an operand location; otherwise, an AFP-register data exception, DXC 1, is recognized.

Mnemonics for the HFP instructions have an R as the last letter when the instruction is in the RR, RRE, or RRF format. Certain letters are used for HFP instructions to represent operand-format length and normalization, as follows:

- F Thirty-two-bit fixed point
- G Sixty-four-bit fixed point

D Long normalized  
 E Short normalized  
 U Short unnormalized  
 W Long unnormalized  
 X Extended normalized

**Note:** In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (short), for example, CER is the mnemonic and R<sub>1</sub>,R<sub>2</sub> the operand designation.

- MULTIPLY AND ADD (MAD, MADR, MAE, MAER)
- MULTIPLY AND SUBTRACT (MSD, MSDR, MSE, MSER)

2. The following additional HFP instructions are available when the HFP-unnormalized-extensions facility is installed:

- MULTIPLY AND ADD UNNORMALIZED (MAY, MAYH, MAYHR, MAYL, MAYLR, MAYR)
- MULTIPLY UNNORMALIZED (MY, MYH, MYHR, MYL, MYLR, MYR)

### Programming Notes:

1. The following additional HFP instructions are available when the HFP-multiply-and-add/subtract facility is installed:

**Explanation:**

A Access exceptions for logical addresses.  
 B<sub>2</sub> B<sub>2</sub> field designates an access register in the access-register mode.  
 C Condition code is set.  
 Da AFP-register data exception.  
 EO HFP-exponent-overflow exception.  
 EU HFP-exponent-underflow exception.  
 FK HFP-divide exception.  
 HM HFP-multiply-add/subtract facility.  
 LS HFP-significance exception.  
 N Instruction is new in z/Architecture as compared to ESA/390.  
 RR RR instruction format.  
 RRE RRE instruction format.  
 RRF RRF instruction format.  
 RX RX instruction format.  
 RXE RXE instruction format.  
 SP Specification exception.  
 SQ HFP-square-root exception.  
 UE HFP unnormalized-extensions facility.

Mnemonic2 Op Code Operands  
 AE '7A' Short HFP  
 AD '6A' Long HFP

The second operand is added to the first operand, and the normalized sum is placed at the first-operand location.

Addition of two HFP numbers consists in characteristic comparison, fraction alignment, and signed fraction addition. The characteristics of the two operands are compared, and the fraction accompanying the smaller characteristic is aligned with the other fraction by a right shift, with its characteristic increased by one for each hexadecimal digit of shift until the two characteristics agree.

When a fraction is shifted right during alignment, the leftmost hexadecimal digit shifted out is retained as a guard digit. The fraction that is not shifted is considered to be extended with a zero in the guard-digit position. When no alignment shift occurs, both operands are considered to be extended with zeros in the guard-digit position. The fractions with signs are then added algebraically to form a signed intermediate sum.

The intermediate-sum fraction consists of seven (short format), 15 (long format), or 29 (extended format) hexadecimal digits, including the guard digit, and a possible carry. If a carry is present, the sum is shifted right one digit position so that the carry becomes the leftmost digit of the fraction, and the characteristic is increased by one.

If the addition produces no carry, the intermediate-sum fraction is shifted left as necessary to eliminate any leading hexadecimal zero digits resulting from the addition, provided the fraction is not zero. Zeros are supplied to the vacated rightmost digits, and the characteristic is reduced by the number of hexadecimal digits of shift. The fraction thus normalized is then truncated on the right to six (short format), 14 (long format), or 28 (extended format) hexadecimal digits. In the extended format, a characteristic is generated for the low-order part, which is 14 less than the high-order characteristic.

The sign of the sum is determined by the rules of algebra, unless all digits of the intermediate-sum fraction are zero, in which case the sign is made plus.

An HFP-exponent-overflow exception exists when a carry from the leftmost position of the intermediate-sum fraction would cause the characteristic of the normalized sum to exceed 127. The operation is completed by making the result characteristic 128 less than the correct value, and a program interrupt

for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. For extended results, the characteristic of the low-order part remains correct.

An HFP-exponent-underflow exception exists when the characteristic of the normalized sum would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

The result fraction is zero when the intermediate-sum fraction, including the guard digit, is zero. With a zero result fraction, the action depends on the setting of the HFP-significance mask bit in the PSW. If the HFP-significance mask bit in the PSW is one, no normalization occurs, the intermediate and final result characteristics are the same, and a program interruption for HFP significance occurs. If the HFP-significance mask bit in the PSW is zero, the program interruption does not occur; instead, the result is made a positive true zero.

For AXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### ***Resulting Condition Code:***

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 --

#### ***Program Exceptions:***

- Access (fetch, operand 2 of AE and AD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- HFP significance
- Specification (AXR only)

**Programming Notes:**

1. An example of the use of the ADD NORMALIZED instruction (AE) is given in Appendix A.
2. Interchanging the two operands in an HFP addition does not affect the value of the sum.
3. The ADD NORMALIZED instruction normalizes the sum but not the operands. Thus, if one or both operands are unnormalized, precision may be lost during fraction alignment.

**ADD UNNORMALIZED**

Mnemonic1 R<sub>1</sub>,R<sub>2</sub> [RR]

Op Code	R <sub>1</sub>	R <sub>2</sub>
0	8	12 15

Mnemonic1 Op Code Operands  
 AUR '3E' Short HFP  
 AWR '2E' Long HFP

Mnemonic2 R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RX]

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>	
0	8	12	16	20	31

Mnemonic2 Op Code Operands  
 AU '7E' Short HFP  
 AW '6E' Long HFP

The second operand is added to the first operand, and the unnormalized sum is placed at the first-operand location.

The execution of ADD UNNORMALIZED is identical to that of ADD NORMALIZED, except that:

1. When no carry is present after the addition, the intermediate-sum fraction is truncated to the proper result-fraction length without a left shift to eliminate leading hexadecimal zeros and without the corresponding reduction of the characteristic.
2. HFP exponent underflow cannot occur.
3. The guard digit does not participate in the recognition of a zero result fraction. A zero result fraction is recognized when the fraction (that is, the intermediate-sum fraction, excluding the guard digit) is zero.

**Resulting Condition Code:**

- 0 Result fraction zero

- 1 Result less than zero
- 2 Result greater than zero
- 3 --

**Program Exceptions:**

- Access (fetch, operand 2 of AU and AW only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP significance

**Programming Notes:**

1. An example of the use of the ADD UNNORMALIZED instruction (AU) is given in Appendix A.
2. Except when the result is made a true zero, the characteristic of the result of ADD UNNORMALIZED is equal to the greater of the two operand characteristics, increased by one if the fraction addition produced a carry, or set to zero if HFP exponent overflow occurred.

**COMPARE**

Mnemonic1 R<sub>1</sub>,R<sub>2</sub> [RR]

Op Code	R <sub>1</sub>	R <sub>2</sub>
0	8	12 15

Mnemonic1 Op Code Operands  
 CER '39' Short HFP  
 CDR '29' Long HFP

Mnemonic2 R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic2 Op Code Operands  
 CXR 'B369' Extended HFP

Mnemonic3 R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RX]

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>	
0	8	12	16	20	31

Mnemonic3 Op Code Operands  
 CE '79' Short HFP  
 CD '69' Long HFP

The first operand is compared with the second operand, and the condition code is set to indicate the result.

The comparison is algebraic and follows the procedure for normalized subtraction, except that the dif-

ference is discarded after setting the condition code and both operands remain unchanged. When the difference, including the guard digit, is zero, the operands are equal. When a nonzero difference is positive or negative, the first operand is high or low, respectively.

An HFP-exponent-overflow, HFP-exponent-underflow, or HFP-significance exception cannot occur.

For CXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### ***Resulting Condition Code:***

- 0 Operands equal
- 1 First operand low
- 2 First operand high
- 3 --

#### ***Program Exceptions:***

- Access (fetch, operand 2 of CE and CD only)
- Data with DXC 1, AFP register
- Specification (CXR only)

#### ***Programming Notes:***

1. Examples of the use of the COMPARE instruction (CDR) are given in Appendix A.
2. An exponent inequality alone is not sufficient to determine the inequality of two operands with the same sign, because the fractions may have different numbers of leading hexadecimal zeros.
3. Numbers with zero fractions compare equal even when they differ in sign or characteristic.

## **CONVERT FROM FIXED**

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]	
Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic	Op Code	Operands
CEFR	'B3B4'	32-bit binary-integer operand, short HFP result
CDFR	'B3B5'	32-bit binary-integer operand, long HFP result
CXFR	'B3B6'	32-bit binary-integer operand, extended HFP result
CEGR	'B3C4'	64-bit binary-integer operand, short HFP result
CDGR	'B3C5'	64-bit binary-integer operand, long HFP result
CXGR	'B3C6'	64-bit binary-integer operand, extended HFP result

The fixed-point second operand is converted to the HFP format, and the normalized result is placed at the first-operand location.

A nonzero result is normalized. A zero result is made a positive true zero.

The second operand is a signed binary integer that is located in the general register designated by R<sub>2</sub>. A 32-bit operand is in bit positions 32-63 of the register.

The result is normalized and rounded toward zero (truncated) before it is placed at the first-operand location.

For CXFR and CXGR, the R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

***Condition Code:*** The code remains unchanged.

#### ***Program Exceptions:***

- Data with DXC 1, AFP register
- Specification (CXFR and CXGR)

## CONVERT TO FIXED

Mnemonic R<sub>1</sub>,M<sub>3</sub>,R<sub>2</sub> [RRF]

Op Code	M <sub>3</sub>		R <sub>1</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic	Op Code	Operands
CFER	'B3B8'	Short HFP operand, 32-bit binary-integer result
CFDR	'B3B9'	Long HFP operand, 32-bit binary-integer result
CFXR	'B3BA'	Extended HFP operand, 32-bit binary-integer result
CGER	'B3C8'	Short HFP operand, 64-bit binary-integer result
CGDR	'B3C9'	Long HFP operand, 64-bit binary-integer result
CGXR	'B3CA'	Extended HFP operand, 64-bit binary-integer result

The HFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by R<sub>1</sub>. A 32-bit result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

The second operand is rounded to an integer value by rounding as specified by the modifier in the M<sub>3</sub> field:

### M<sub>3</sub> Effective Rounding Method

- 0 Round toward 0
- 1 Round to nearest with ties away from 0
- 4 Round to nearest with ties to even
- 5 Round toward 0
- 6 Round toward +∞
- 7 Round toward -∞

For details on rounding see the section “Rounding Methods” on page 9-13.

A modifier other than 0, 1, or 4-7 is invalid.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

If the rounded result would have a value exceeding the range that can be represented in the result format, the largest (in magnitude) representable number of the same sign as the source is placed at the target location, and condition code 3 is set.

HFP exponent underflow is not recognized because small values are rounded to one (with the appropriate sign) or to zero, depending on the rounding mode.

The M<sub>3</sub> field must designate a valid modifier; otherwise, a specification exception is recognized. For CFXR and CGXR, the R<sub>2</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

### Resulting Condition Code:

- 0 Source was zero
- 1 Source was less than zero
- 2 Source was greater than zero
- 3 Special case

### Program Exceptions:

- Data with DXC 1, AFP register
- Specification

## DIVIDE

Mnemonic1 R<sub>1</sub>,R<sub>2</sub> [RR]

Op Code	R <sub>1</sub>	R <sub>2</sub>
0	8	12 15

Mnemonic1	Op Code	Operands
DER	'3D'	Short HFP
DDR	'2D'	Long HFP

Mnemonic2 R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic2	Op Code	Operands
DXR	'B22D'	Extended HFP

Mnemonic3 R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RX]

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
0	8	12	16	20 31

Mnemonic3	Op Code	Operands
DE	'7D'	Short HFP
DD	'6D'	Long HFP

The first operand (the dividend) is divided by the second operand (the divisor), and the normalized quotient is placed at the first-operand location. No remainder is preserved.

HFP division consists in characteristic subtraction and fraction division. The operands are first normalized to eliminate leading hexadecimal zeros. The difference between the dividend and divisor characteristics of the normalized operands, plus 64, is used as the characteristic of an intermediate quotient.

All dividend and divisor fraction digits participate in forming the fraction of the intermediate quotient. The intermediate-quotient fraction can have no leading hexadecimal zeros, but a right shift of one digit position may be necessary, with this causing an increase of the characteristic by one. The fraction is then truncated to the proper result-fraction length.

An HFP-exponent-overflow exception exists when the characteristic of the final quotient would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. If, for extended results, the low-order characteristic would also exceed 127, it too is decreased by 128.

An HFP-exponent-underflow exception exists when the characteristic of the final quotient would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

HFP exponent underflow does not occur when the characteristic of an operand becomes less than zero during normalization of the operands or when the intermediate-quotient characteristic is less than zero, as long as the final quotient can be represented with the correct characteristic.

When the divisor fraction is zero, an HFP-divide exception is recognized. This includes the case of division of zero by zero.

When the dividend fraction is zero but the divisor fraction is nonzero, the quotient is made a positive true zero. No HFP exponent overflow or HFP exponent underflow occurs.

The sign of the quotient is the exclusive or of the operand signs, except that the sign is always plus when the quotient is made a positive true zero.

For DXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### **Program Exceptions:**

- Access (fetch, operand 2 of DE and DD only)
- Data with DXC 1, AFP register
- HFP divide
- HFP exponent overflow
- HFP exponent underflow
- Specification (DXR only)

**Programming Note:** Examples of the use of the DIVIDE instruction (DER) are given in Appendix A.

## **HALVE**

Mnemonic R<sub>1</sub>,R<sub>2</sub> [RR]

Op Code	R <sub>1</sub>	R <sub>2</sub>
0	8	12 15

Mnemonic	Op Code	Operands
HER	'34'	Short HFP
HDR	'24'	Long HFP

The second operand is divided by 2, and the normalized quotient is placed at the first-operand location.

The fraction of the second operand is shifted right one bit position, placing the contents of the rightmost bit position in the leftmost bit position of the guard digit, and a zero is supplied to the leftmost bit position of the fraction. The intermediate result, including the guard digit, is then normalized, and the final result is truncated to the proper length.

An HFP-exponent-underflow exception exists when the characteristic of the final result would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result charac-

teristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero.

When the fraction of the second operand is zero, the result is made a positive true zero, and no HFP exponent underflow occurs.

The sign of the result is the same as that of the second operand, except that the sign is always plus when the quotient is made a positive true zero.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Data with DXC 1, AFP register
- HFP exponent underflow

#### Programming Notes:

1. An example of the use of the HALVE instruction (HDR) is given in Appendix A.
2. With short and long operands, the halve operation is identical to a divide operation with the number 2 as divisor. Similarly, the result of HDR is identical to that of MD or MDR with one-half as a multiplier, and the result of HER is identical to that of MEE or MEER with one-half as a multiplier.

## LOAD AND TEST

Mnemonic1	R <sub>1</sub> ,R <sub>2</sub>	[RR]
Op Code	R <sub>1</sub>	R <sub>2</sub>
0	8	12 15

Mnemonic1	Op Code	Operands
LTER	'32'	Short HFP
LTDR	'22'	Long HFP

Mnemonic2	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
Op Code		R <sub>1</sub> R <sub>2</sub>
0	16	24 28 31

Mnemonic2	Op Code	Operands
LTXR	'B362'	Extended HFP

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

For short and long operands, the second operand is placed unchanged in the first-operand location.

For extended operands, the high-order sign and the entire fraction of the source are placed unchanged in the result, and the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a true zero with the same sign as the source (the high-order and low-order sign bits of the result are the same as the high-order sign bit of the source).

For LTXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### Resulting Condition Code:

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 --

#### Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LTXR only)

**Programming Note:** When, for LTER and LTDR, the same register is designated as the first-operand and second-operand location, the operation is equivalent to a test without data movement.

## LOAD COMPLEMENT

Mnemonic1	R <sub>1</sub> ,R <sub>2</sub>	[RR]
Op Code	R <sub>1</sub>	R <sub>2</sub>
0	8	12 15

Mnemonic1	Op Code	Operands
LCER	'33'	Short HFP
LCDR	'23'	Long HFP

Mnemonic2 R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic2 Op Code Operands  
LCXR 'B363' Extended HFP

The second operand is placed at the first-operand location with the sign bit inverted.

The sign bit is inverted even if the operand is zero. For all operand lengths, the source fraction is placed unchanged in the result.

For short and long operands, the source characteristic is placed unchanged in the result.

For extended operands, the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a true zero with the sign inverted from the source (the high-order and low-order sign bits of the result are inverted from the high-order sign bit of the source).

For LCXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### **Resulting Condition Code:**

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 --

#### **Program Exceptions:**

- Data with DXC 1, AFP register
- Specification (LCXR only)

## **LOAD FP INTEGER**

Mnemonic R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic Op Code Operands  
FIER 'B377' Short HFP  
FIDR 'B37F' Long HFP  
FIXR 'B367' Extended HFP

The second operand is truncated (rounded toward zero) to an integer value in the same floating-point format, and the normalized result is placed at the first-operand location.

A nonzero result is normalized. A zero result is made a positive true zero.

For FIXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### **Program Exceptions:**

- Data with DXC 1, AFP register
- Specification (FIXR only)

#### **Programming Notes:**

1. LOAD FP INTEGER truncates (rounds toward zero) an HFP number to an integer value. These integers, which remain in the HFP format, should not be confused with binary integers, which use a fixed-point format.
2. If the HFP operand has a large enough exponent so that it is already an integer, the result value remains the same, except that an unnormalized operand is normalized, and an operand with a zero fraction is changed to a positive true zero.

## LOAD LENGTHENED

Mnemonic1	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
Op Code	R <sub>1</sub> R <sub>2</sub>	

Mnemonic1	Op Code	Operands
LDER	'B324'	Short HFP operand 2, long HFP operand 1
LXDR	'B325'	Long HFP operand 2, extended HFP operand 1
LXER	'B326'	Short HFP operand 2, extended HFP operand 1

Mnemonic2	R <sub>1</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXE]
Op Code	R <sub>1</sub> X <sub>2</sub> B <sub>2</sub> D <sub>2</sub>       Op Code	0 8 12 16 20 32 40 47

Mnemonic2	Op Code	Operands
LDE	'ED24'	Short HFP operand 2, long HFP operand 1
LXD	'ED25'	Long HFP operand 2, extended HFP operand 1
LXE	'ED26'	Short HFP operand 2, extended HFP operand 1

The second operand is extended to a longer format, and the result is placed at the first-operand location.

For all operand lengths, the source fraction is extended with zeros and placed in the result. The sign bit of the result is set the same as the sign of the source even when the result is made a true zero.

For long results, the source characteristic is placed unchanged in the result.

For extended results, the low-order sign is set equal to the high-order sign. If the fraction is nonzero, the source characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the fraction is zero, the result is made a true zero with the same sign as the source (the high-order and low-order sign bits of the result are the same as the sign bit of the source).

For LXD, LXDR, LXE, and LXER, the R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**Program Exceptions:**

- Access (fetch, operand 2 of LDE, LXE, and LXD only)
- Data with DXC 1, AFP register
- Specification (LXE, LXER, LXD, LXDR)

## LOAD NEGATIVE

Mnemonic1	R <sub>1</sub> ,R <sub>2</sub>	[RR]
Op Code	R <sub>1</sub> R <sub>2</sub>	0 8 12 15

Mnemonic1	Op Code	Operands
LNER	'31'	Short HFP
LNDR	'21'	Long HFP

Mnemonic2	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
Op Code	R <sub>1</sub> R <sub>2</sub>	0 16 24 28 31

Mnemonic2	Op Code	Operands
LNXR	'B361'	Extended HFP

The second operand is placed at the first-operand location with the sign bit made one.

The sign bit is made one even if the operand is zero. For all operand lengths, the source fraction is placed unchanged in the result.

For short and long operands, the source characteristic is placed unchanged in the result.

For extended operands, the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a negative true zero (the high-order and low-order sign bits of the result are set to one).

For LNXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

### Resulting Condition Code:

- 0 Result is zero
- 1 Result is less than zero
- 2 --
- 3 --

**Program Exceptions:**

- Data with DXC 1, AFP register
- Specification (LNXR only)

**LOAD POSITIVE**Mnemonic1 R<sub>1</sub>,R<sub>2</sub> [RR]

Op Code	R <sub>1</sub>	R <sub>2</sub>
0	8	12 15

Mnemonic1 Op Code Operands

LPER '30' Short HFP  
LPDR '20' Long HFPMnemonic2 R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic2 Op Code Operands

LPXR 'B360' Extended HFP

The second operand is placed at the first-operand location with the sign bit made zero.

For all operand lengths, the sign bit is made zero, and the source fraction is placed unchanged in the result.

For short and long operands, the source characteristic is placed unchanged in the result.

For extended operands, the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a positive true zero (the high-order and low-order sign bits of the result are set to zero).

For LPXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

- |   |                             |
|---|-----------------------------|
| 0 | Result is zero              |
| 1 | --                          |
| 2 | Result is greater than zero |
| 3 | --                          |

**Program Exceptions:**

- Data with DXC 1, AFP register
- Specification (LPXR only)

**LOAD ROUNDED**Mnemonic1 R<sub>1</sub>,R<sub>2</sub> [RR]

Op Code	R <sub>1</sub>	R <sub>2</sub>
0	8	12 15

Mnemonic1 Op Code Operands

LEDR '35' Long HFP operand 2, short HFP operand 1  
LDXR '25' Extended HFP operand 2, long HFP operand 1

The above mnemonics are alternatives to the following older mnemonics that are less descriptive of operand lengths:

LRER '35'	Long HFP operand 2, short HFP operand 1
LRDR '25'	Extended HFP operand 2, long HFP operand 1

Mnemonic2 R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic2 Op Code Operands

LEXR 'B366' Extended HFP operand 2, short HFP operand 1

The second operand is rounded to a shorter format, and the result is placed at the first-operand location.

Rounding consists in adding a one to the leftmost bit position of the second operand that is to be dropped and propagating any carry through the fraction. The sign of the second operand is ignored, and addition is performed as if the fraction were positive.

If rounding causes a carry out of the leftmost hexadecimal digit position of the fraction, the fraction is shifted right one digit position so that the carry becomes the leftmost digit of the fraction, and the characteristic is increased by one.

The intermediate fraction is then truncated to the proper result-fraction length. For LEDR and LEXR, the result replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged. For LDXR, the 64-bit result is placed in a floating-point register, not a floating-point register pair.

The sign of the result is the same as the sign of the second operand. There is no normalization to eliminate leading zeros.

An HFP-exponent-overflow exception exists when shifting the fraction right would cause the characteristic to exceed 127. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct.

HFP-exponent-underflow and HFP-significance exceptions cannot occur.

For LDXR (or LRDR) and LEXR, the  $R_2$  field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Data with DXC 1, AFP register
- HFP exponent overflow
- Specification (LDXR, LEXR, LRDR)

**Programming Note:** The sign of the rounded result is the same as the sign of the operand, even when the result is zero.

## MULTIPLY

Mnemonic1  $R_1, R_2$  [RRE]

Op Code		$R_1$	$R_2$
0	16	24	28 31

Mnemonic1 Op Code Operands  
MEER 'B337' Short HFP

MXR '26' Extended HFP  
MDER '3C' Short HFP multiplier and multiplicand, long HFP product  
MXDR '27' Long HFP multiplier and multiplicand, extended HFP product

The above mnemonic MDER is an alternative to the following older mnemonic that is less descriptive of operand lengths:

MER '3C' Short HFP multiplier and multiplicand, long HFP product

Mnemonic3  $R_1, D_2(X_2, B_2)$  [RXE]

Op Code	$R_1$	$X_2$	$B_2$	$D_2$		Op Code
0	8	12	16	20	32	40 47

Mnemonic3 Op Code Operands  
MEE 'ED37' Short HFP

Mnemonic4  $R_1, D_2(X_2, B_2)$  [RX]

Op Code	$R_1$	$X_2$	$B_2$	$D_2$	31
0	8	12	16	20	31

Mnemonic4 Op Code Operands  
MD '6C' Long HFP  
MDE '7C' Short HFP multiplier and multiplicand, long HFP product  
MXD '67' Long HFP multiplier and multiplicand, extended HFP product

The above mnemonic MDE is an alternative to the following older mnemonic that is less descriptive of operand lengths:

ME '7C' Short HFP multiplier and multiplicand, long HFP product

The normalized product of the second operand (the multiplier) and the first operand (the multiplicand) is placed at the first-operand location.

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The operands are first normalized to eliminate leading hexadecimal zeros. The sum of the characteristics of the normalized operands, less 64, is used as the characteristic of the intermediate product.

The fraction of the intermediate product is the exact product of the normalized operand fractions. If the intermediate-product fraction has one leading hexadecimal zero digit, the fraction is shifted left one digit position, bringing the contents of the guard-digit position into the rightmost position of the result fraction, and the intermediate-product characteristic is reduced by one. The fraction is then truncated to the proper result-fraction length.

For MDE and MDER, the multiplier and multiplicand fractions have six hexadecimal digits; the product fraction has the full 14 digits of the long format, with the two rightmost fraction digits always zeros. For MEE and MEER, the multiplier and multiplicand fractions have six digits, and the final product fraction is truncated to six digits; the result, as for all short-for-

mat results, replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged.

For MD and MDR, the multiplier and multiplicand fractions have 14 digits, and the final product fraction is truncated to 14 digits. For MXD and MXDR, the multiplier and multiplicand fractions have 14 digits, with the multiplicand occupying the high-order part of the first operand; the final product fraction contains 28 digits and is an exact product of the operand fractions. For MXR, the multiplier and multiplicand fractions have 28 digits, and the final product fraction is truncated to 28 digits.

An HFP-exponent-overflow exception exists when the characteristic of the final product would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. If, for extended results, the low-order characteristic would also exceed 127, it too is decreased by 128.

HFP exponent overflow is not recognized when the intermediate-product characteristic is initially 128 but is brought back within range by normalization.

An HFP-exponent-underflow exception exists when the characteristic of the final product would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

HFP exponent underflow does not occur when the characteristic of an operand becomes less than zero during normalization of the operands, as long as the final product can be represented with the correct characteristic.

If either or both operand fractions are zero, the result is made a positive true zero, and no HFP exponent overflow or HFP exponent underflow occurs.

The sign of the product is the exclusive or of the operand signs, except that the sign is always plus when the result is made a true zero.

The R<sub>1</sub> field for MXD, MXDR, and MXR, and the R<sub>2</sub> field for MXR must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Access (fetch, operand 2 of MDE, MEE, MD, and MXD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- Specification (MXD, MXDR, MXR)

#### Programming Notes:

1. An example of the use of the MULTIPLY instruction (MDR) is given in Appendix A.
2. Interchanging the two operands in an HFP multiplication does not affect the value of the product.

## MULTIPLY AND ADD

Mnemonic1 R<sub>1</sub>,R<sub>3</sub>,R<sub>2</sub> [RRF]

Op Code	R <sub>1</sub>	///	R <sub>3</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic1 Op Code Operands

MAER	'B32E'	Short HFP
MADR	'B33E'	Long HFP

Mnemonic2 R<sub>1</sub>,R<sub>3</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RXF]

Op Code	R <sub>3</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>	R <sub>1</sub>	///	Op Code
0	8	12	16	20	32	36	40 47

Mnemonic2 Op Code Operands

MAE	'ED2E'	Short HFP
MAD	'ED3E'	Long HFP

## MULTIPLY AND SUBTRACT

Mnemonic1	R <sub>1</sub> ,R <sub>3</sub> ,R <sub>2</sub>	[RRF]
Op Code	R <sub>1</sub>	R <sub>3</sub> R <sub>2</sub>

Mnemonic1	Op Code	Operands
MSER	'B32F'	Short HFP
MSDR	'B33F'	Long HFP

Mnemonic2	R <sub>1</sub> ,R <sub>3</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXF]
Op Code	R <sub>3</sub> X <sub>2</sub> B <sub>2</sub> D <sub>2</sub> R <sub>1</sub>	Op Code

Mnemonic2	Op Code	Operands
MSE	'ED2F'	Short HFP
MSD	'ED3F'	Long HFP

The third operand is multiplied by the second operand, and then the first operand is added to or subtracted from the product. The sum or difference is placed at the first-operand location. The MULTIPLY AND ADD and MULTIPLY AND SUBTRACT operations may be summarized as:

$$\text{op}_1 = \text{op}_3 \cdot \text{op}_2 \pm \text{op}_1$$

The third and second HFP operands are multiplied, forming an intermediate product, and the first operand is then added (or subtracted) algebraically to (or from) the intermediate product, forming an intermediate result. The exponent and fraction of the intermediate product and intermediate result are maintained exactly. The intermediate result, if nonzero, is normalized and truncated to the operand format and then placed at the first-operand location.

The sign of the result is determined by the rules of algebra, unless the intermediate-result fraction is zero, in which case the result is made a positive true zero.

An HFP-exponent-overflow exception exists when the characteristic of the normalized result would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct.

HFP exponent overflow is not recognized on intermediate values, provided the normalized result can be represented with the correct characteristic.

An HFP-exponent-underflow exception exists when the characteristic of the normalized result would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero.

HFP exponent underflow is not recognized on input operands and intermediate values, provided the normalized result can be represented with the correct characteristic.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch, operand 2 of MAE, MAD, MSE, MSD)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- Operation (if the HFP multiply-add/subtract facility is not installed)

**Programming Note:** MULTIPLY AND ADD (SUBTRACT) differs from MULTIPLY followed by ADD (SUBTRACT) NORMALIZED in the following ways:

1. The product is maintained to full precision, and overflow and underflow are not recognized on the product.
2. The HFP-significance exception is not recognized for MULTIPLY AND ADD (SUBTRACT).
3. ADD (SUBTRACT) NORMALIZED maintains only a single guard digit and does not prenormalize input operands; thus, in some cases, an unnormalized input operand may cause loss of precision in the result. MULTIPLY AND ADD (SUBTRACT) maintains the entire intermediate sum (difference), which is normalized before the truncation operation is performed; thus, unnormalized operands do not cause any additional loss of precision.
4. On most models, the execution time of MULTIPLY AND ADD (SUBTRACT) is less than the combined execution time of MULTIPLY followed

by ADD (SUBTRACT) NORMALIZED. The performance of MULTIPLY AND ADD (SUBTRACT) may be severely degraded in the case of unnormalized input operands.

## MULTIPLY AND ADD UNNORMALIZED

Mnemonic1 R<sub>1</sub>,R<sub>3</sub>,R<sub>2</sub> [RRF]

Op Code	R <sub>1</sub>	////	R <sub>3</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic1 Op Code Operands

MAYR	'B33A'	Long HFP sources, extended HFP result
MAYHR	'B33C'	Long HFP sources, high-order part of extended HFP result
MAYLR	'B338'	Long HFP sources, low-order part of extended HFP result

Mnemonic2 R<sub>1</sub>,R<sub>3</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RXF]

Op Code	R <sub>3</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>	R <sub>1</sub>	////	Op Code
0	8	12	16	20	32	36	40 47

Mnemonic2 Op Code Operands

MAY	'ED3A'	Long HFP sources, extended HFP result
MAYH	'ED3C'	Long HFP sources, high-order part of extended HFP result
MAYL	'ED38'	Long HFP sources, low-order part of extended HFP result

The second and third HFP operands are multiplied, forming an intermediate product; the first operand (addend) is then added algebraically to the intermediate product to form an intermediate sum; the intermediate-sum fraction is truncated on the left or on the right, if need be, to form an intermediate extended result. All (or a part) of the intermediate extended result is placed in the floating-point-register pair (or floating-point register) designated by the R<sub>1</sub> field. The operands, intermediate values, and results are not normalized to eliminate leading hexadecimal zeros.

The MULTIPLY AND ADD UNNORMALIZED operations may be summarized as:

$$t_1 \leftarrow op_3 \bullet op_2 + op_1$$

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The sum of the characteristics of the second and third operands, less 64, is used as the characteristic of the high-order part of the intermediate product; this value is

independent of whether the result fraction is zero. The characteristic of the intermediate product is maintained correctly and does not wrap.

In all cases, the second- and third-operand fractions have 14 digits; the intermediate-product fraction contains 28 digits and is an exact product of the operand fractions. The intermediate-product fraction is not inspected for leading hexadecimal zero digits and is used without shifting in the subsequent addition.

In all cases, the first operand is located in the floating-point register designated by the R<sub>1</sub> field and the first-operand fraction has 14 digits.

Addition of two HFP numbers consists in characteristic comparison, fraction alignment, and signed fraction addition. The characteristics of the intermediate product and the addend are compared. If the characteristics are equal, no alignment is required. If the characteristic of the addend is smaller than the characteristic of the product, the fraction of the addend is aligned with the product fraction by a right shift, with its characteristic increased by one for each hexadecimal digit of shift. If the characteristic of the addend is larger than the characteristic of the product, the fraction of the addend is aligned with the product fraction by a left shift, with its characteristic decreased by one for each hexadecimal digit of shift. Shifting continues until the two characteristics agree. All hexadecimal digits shifted out are preserved and participate in the subsequent addition.

After alignment, the fractions with signs are then added algebraically to form a signed intermediate sum. The fraction of the intermediate sum is maintained exactly. The intermediate-sum fraction is not inspected for leading hexadecimal zero digits and is not shifted. Only those 28 hexadecimal digits of the intermediate-sum fraction which are aligned with the 28 hexadecimal digits of the intermediate-product fraction are used as the fraction of the intermediate extended-result.

The high-order characteristic of the intermediate extended result is set to the characteristic of the intermediate product, modulo 128. The low-order characteristic of the intermediate extended result is set to 14 less than the high-order characteristic, modulo 128. Wrap-around of the characteristic is independent of whether the result fraction is zero.

The sign of the result is determined by the rules of algebra, unless the entire intermediate-sum fraction

is zero, in which case the sign of the result is made positive.

For MAY and MAYR, the entire intermediate extended result is placed in the floating-point register-pair designated by the R<sub>1</sub> field; the R<sub>1</sub> field may designate either the lower-numbered or higher-numbered register of a floating-point-register pair. For MAYH and MAYHR, the high-order part of the intermediate extended result is placed in the floating-point register designated by the R<sub>1</sub> field and the low-order part is discarded. For MAYL and MAYLR, the low-order part of the intermediate extended result is placed in the floating-point register designated by the R<sub>1</sub> field and the high-order part is discarded.

HFP-exponent-overflow and HFP-exponent-underflow exceptions are not recognized. Characteristics of the intermediate extended result wrap-around modulo 128 and no exception is reported.

**Condition Code:** The code remains unchanged.

#### Program Exceptions:

- Access (fetch, operand 2 of MAYH, MAY, and MAYL only)
- Data with DXC 1, AFP register
- Operation (if the HFP-unnormalized-extensions facility is not installed)

#### Programming Notes:

1. While performance of MULTIPLY AND ADD may be severely degraded for the case of unnormalized input operands, this is not the case for MULTIPLY AND ADD UNNORMALIZED.
2. MULTIPLY AND ADD UNNORMALIZED can be used to efficiently perform multiple precision arithmetic on numbers of any arbitrary size. This is accomplished by organizing the numbers into big digits of 52 bits each, with each big digit maintained as an integer in the HFP long format. Using a radix of 2<sup>52</sup> and big digits which can hold up to 56 bits provides a redundant representation. This redundant representation permits multiplication and addition using a “carry save” technique and permits maximum utilization of the floating-point pipeline.
3. By setting the multiplier to an integer value of 1 with the proper characteristic, the multiplicand

can be scaled by any power of 16 and then added to the addend. This permits, for example, adding the “carry” from one stage of a multiplication to the “sum” of the next stage to the left. In the same manner, the “sum” of one stage can be scaled to be added to the “carry” of the stage to the right.

4. In the first round of a multiply and accumulate, the step of clearing the accumulated value to zero, may be avoided by using the MULTIPLY UNNORMALIZED instead of MULTIPLY AND ADD UNNORMALIZED.
5. For additional notes concerning the unnormalized operations see the programming notes under the MULTIPLY UNNORMALIZED instruction.

## MULTIPLY UNNORMALIZED

Mnemonic1 R<sub>1</sub>,R<sub>3</sub>,R<sub>2</sub> [RRF]

Op Code	R <sub>1</sub>	///	R <sub>3</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic1 Op Code Operands

MYR	'B33B'	Long HFP multiplier and multiplicand, extended HFP product
MYHR	'B33D'	Long HFP multiplier and multiplicand, high-order part of extended HFP product
MYLR	'B339'	Long HFP multiplier and multiplicand, low-order part of extended HFP product

Mnemonic2 R<sub>1</sub>,R<sub>3</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RXF]

Op Code	R <sub>3</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>	R <sub>1</sub>	///	Op Code
0	8	12	16	20	32	36	40 47

Mnemonic2 Op Code Operands

MY	'ED3B'	Long HFP multiplier and multiplicand, extended HFP product
MYH	'ED3D'	Long HFP multiplier and multiplicand, high-order part of extended HFP product
MYL	'ED39'	Long HFP multiplier and multiplicand, low-order part of extended HFP product

The second and third HFP operands are multiplied, forming an intermediate product, which, in turn, is used to form an intermediate extended result. All (or a part) of the intermediate extended result is placed in the floating-point-register pair (or floating-point register) designated by the R<sub>1</sub> field. The operands, intermediate values, and results are not normalized to eliminate leading hexadecimal zeros.

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The sum of the characteristics of the second and third operands, less 64, is used as the characteristic of the high-order part of the intermediate product; this value is independent of whether the result fraction is zero. The characteristic of the intermediate product is maintained correctly and does not wrap.

The high-order characteristic of the intermediate extended result is set to the characteristic of the intermediate product, modulo 128. The low-order characteristic of the intermediate extended result is set to 14 less than the high-order characteristic, modulo 128. Wrap-around of the characteristic is independent of whether the result fraction is zero.

In all cases, the second- and third-operand fractions have 14 digits; the intermediate-product fraction contains 28 digits and is an exact product of the operand fractions. The intermediate-product fraction is not inspected for leading hexadecimal zero digits and is used without shifting as the fraction of the intermediate extended result.

The sign of the result is the exclusive or of the operand signs, including the case when the result fraction is zero.

For MY and MYR, the entire intermediate extended result is placed in the floating-point-register pair designated by the R<sub>1</sub> field. For MYH and MYHR, the high-order part of the intermediate extended result is placed in the floating-point register designated by the R<sub>1</sub> field and the low-order part is discarded. For MYL and MYLR, the low-order part of the intermediate extended result is placed in the floating-point register designated by the R<sub>1</sub> field and the high-order part is discarded.

HFP-exponent-overflow and HFP-exponent-underflow exceptions are not recognized. Characteristics of the intermediate extended result wrap-around modulo 128 and no exception is reported.

The R<sub>1</sub> field for MY and MYR must designate a valid floating-point-register pair. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### **Program Exceptions:**

- Access (fetch, operand 2 of MYH, MY, and MYL only)
- Data with DXC 1, AFP register
- Operation (if the HFP-unnormalized-extensions facility is not installed)
- Specification (MY and MYR)

#### **Programming Notes:**

1. The formal definition of Long HFP numbers is in terms of a 14-digit fraction and a signed exponent in “excess-64 notation”. But, without change in function, these numbers can also be described as having a 14-digit integer and a signed exponent in “excess-78 notation”. When using the unnormalized instructions, the programmer may find it more convenient to consider these values in the later terms rather than the former. Thus, in these terms, MULTIPLY UNNORMALIZED multiplies two 14-digit integers to produce a 28-digit integer result. The characteristic of the low-order part is the sum of the operand characteristics less 78 and the high-order characteristic is set 14 larger than the low-order part. When considered as described above, MULTIPLY UNNORMALIZED provides the exact 28-digit integer product of two 14-digit integers.
2. Rather than using MY (or MYR) to provide the entire 28-digits in a floating-point-register pair, the programmer may find it more convenient to issue two separate instructions, MYH and MYL (or MYHR and MYLR), to place the high-order part and low-order part in any floating-point register. It is expected that on most machines, the performance of these two approaches is essentially the same.
3. The MULTIPLY UNNORMALIZED instruction format designates three operand locations and can be used to produce a product without overlaying the source operands. In many cases this saves an extra load.

## SQUARE ROOT

Mnemonic1	R <sub>1</sub> ,R <sub>2</sub>	[RRE]		
Op Code		R <sub>1</sub>	R <sub>2</sub>	
0	16	24	28	31

Mnemonic1	Op Code	Operands
SQER	'B245'	Short HFP
SQDR	'B244'	Long HFP
SQXR	'B336'	Extended HFP

Mnemonic2	R <sub>1</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXE]					
Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>		Op Code	
0	8	12	16	20	32	40	47

Mnemonic2	Op Code	Operands
SQE	'ED34'	Short HFP
SQD	'ED35'	Long HFP

The normalized and rounded square root of the second operand is placed at the first-operand location.

When the fraction of the second operand is zero, the sign and characteristic of the second operand are ignored, and the operation is completed by placing a positive true zero at the first-operand location.

If the second operand is less than zero, an HFP square-root exception is recognized.

If the second operand is normalized and greater than zero, the characteristic, fraction, and sign of the result are produced as follows:

- The result characteristic is one-half of the sum of the operand characteristic and either 64, if the operand characteristic is even, or 65, if it is odd.
- If the operand characteristic is odd, the operand fraction is shifted right one digit position, the rightmost digit entering the guard-digit position.
- An intermediate-result fraction is produced by computing without rounding the square root of the operand fraction, after any right shift as described. The intermediate-result fraction consists of the 29 most significant hexadecimal digits of the square-root result in the extended format, 15 in the long format, or seven in the short format, where all three formats include a guard digit on the right.
- A one is added to the leftmost bit of the guard digit of the intermediate result, any carry is prop-

agated to the left, and the guard digit is dropped to produce the result fraction.

- The result sign is made plus.

If the second operand is unnormalized and greater than zero, the operand is first normalized. The operation then proceeds as for normalized operands.

For SQXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### Program Exceptions:

- Access (fetch, operand 2 of SQE and SQD only)
- Data with DXC 1, AFP register
- HFP square root
- Specification (SQXR only)

### Programming Notes:

- The use of the SQUARE ROOT instruction with short operands (SQER) is illustrated by the examples in the following table:

Operand (hex)	Decimal Value	Result (hex)	Decimal Value
42 190000	25.0	41 500000	5.0
40 400000	0.250	40 800000	0.50
40 800000	0.50	40 B504F3	0.7071...
41 800000	8.0	41 2D413D	2.8284...

- The result fraction is correctly normalized without any further left or right shifts of the intermediate-result fraction and without any further exponent adjustment. Rounding cannot cause a carry out of the leftmost digit.
- Although a characteristic greater than 127 or less than zero may temporarily be generated during the operation, the result characteristic is always within the representable range, and no HFP exponent overflow or underflow occurs.

Specifically, the smallest nonzero operand in the long format consists of a one bit, preceded on the left by 63 zeros. This operand is an unnormalized number with a value of  $16^{-78}$ , and its square root is  $16^{-39}$ . The normalized representation of this result has a characteristic of 26 (decimal). Similarly, the square root of the largest representable operand has a characteristic of 96

(decimal). The instruction, therefore, cannot produce a nonzero result with a characteristic outside the range of 26 to 96.

## SUBTRACT NORMALIZED

Mnemonic1 R<sub>1</sub>,R<sub>2</sub> [RR]

Op Code	R <sub>1</sub>	R <sub>2</sub>
0	8	12 15

Mnemonic1	Op Code	Operands
SER	'3B'	Short HFP
SDR	'2B'	Long HFP
SXR	'37'	Extended HFP

Mnemonic2 R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RX]

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
0	8	12	16	20 31

Mnemonic2	Op Code	Operands
SE	'7B'	Short HFP
SD	'6B'	Long HFP

The second operand is subtracted from the first operand, and the normalized difference is placed at the first-operand location.

The execution of SUBTRACT NORMALIZED is identical to that of ADD NORMALIZED, except that the second operand participates in the operation with its sign bit inverted.

For SXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

### Resulting Condition Code:

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 --

### Program Exceptions:

- Access (fetch, operand 2 of SE and SD only)

- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- HFP significance
- Specification (SXR only)

## SUBTRACT UNNORMALIZED

Mnemonic1 R<sub>1</sub>,R<sub>2</sub> [RR]

Op Code	R <sub>1</sub>	R <sub>2</sub>
0	8	12 15

Mnemonic1	Op Code	Operands
SUR	'3F'	Short HFP
SWR	'2F'	Long HFP

Mnemonic2 R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RX]

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
0	8	12	16	20 31

Mnemonic2	Op Code	Operands
SU	'7F'	Short HFP
SW	'6F'	Long HFP

The second operand is subtracted from the first operand, and the unnormalized difference is placed at the first-operand location.

The execution of SUBTRACT UNNORMALIZED is identical to that of ADD UNNORMALIZED, except that the second operand participates in the operation with its sign bit inverted.

### Resulting Condition Code:

- 0 Result fraction zero
- 1 Result less than zero
- 2 Result greater than zero
- 3 --

### Program Exceptions:

- Access (fetch, operand 2 of SU and SW only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP significance

## Binary-Floating-Point Facility

The binary-floating-point (BFP) facility provides instructions to operate on binary (radix-2) floating-point data.

BFP provides a number of important advantages over hexadecimal floating point (HFP):

- Greater precision and exponent range (except for numbers in the short format where HFP has the greater range).
- Automatic rounding to the nearest value for all arithmetic operations. There are directed-rounding options that may be used instead.
- Special entities of “infinity” and “Not-a-Number” (NaN), which are accepted and handled by arithmetic operations in a reasonable fashion. They provide better defaults for exponent overflow and invalid operations (such as division of zero by zero). This allows most programs to continue running without hiding such errors and without using specialized exception handlers.
- Exponent underflow gives “subnormal” numbers as the default, which provides more consistent results than the abrupt result of zero produced by the HFP instructions.
- The greater exponent range makes exponent overflow and underflow in correctly written programs very unlikely, so that programmers may often be able to ignore these conditions.
- Both mask and flag bits are provided for all IEEE exceptions. The mask bits enable or disable interruptions. When interruptions are disabled, the flag bits keep track of exceptions during execution so that warning messages may be issued.
- Programs can be migrated from and to workstations and other systems using different architectures and still give consistent results, provided that floating-point operations on the other systems also conform to ANSI/IEEE Standard 754-1985. This does not mean, however, that bit-wise compatible results can be guaranteed, because

the standard allows implementation flexibility, especially in the presence of exceptions.

**Programming Note:** The bit representation of the BFP data formats in storage is defined to be left-to-right in a manner that is uniform for all numeric operands in the z/Architecture architecture. Although the format diagrams in ANSI/IEEE Standard 754-1985 appear to use the same left-to-right bit sequence, the standard only defines the meaning of the bits without specifying how they appear in storage; the storage arrangement is left to the implementation. Several implementations in fact use other sequences; this may affect programs which are dependent on the bit representation of floating-point data in storage.

## Floating-Point-Control (FPC) Register

The floating-point-control (FPC) register is a 32-bit register that contains mask bits, flag bits, a data-exception code, and two rounding-mode fields. The FPC register is described in the section “Floating-Point-Control (FPC) Register” on page 9-9. An overview of the FPC register is shown in Figure 9-5 on page 9-9. Details are shown in Figure 9-6 on page 9-9, Figure 9-7 on page 9-9, and in Figure 9-8 on page 9-10. (In Figure 9-6 on page 9-9, the abbreviations “IM” and “SF” are based on the terms “interrupt mask” and “status flag,” respectively.)

The bits of the FPC register are often referred to as, for example, FPC 1.0, meaning bit 0 of byte 1 of the register.

---

## BFP Arithmetic

### BFP Data Formats

Binary-floating-point data may be represented in any of three formats: short, long, or extended.

#### BFP Short Format

S	Exponent+127 (8 bits)	Fraction (23 bits)
0 1	9	31

Figure 19-1. BFP Short Format (4 bytes)

When an operand in the BFP short format is loaded into a floating-point register, it occupies the left half of the register, and the right half remains unchanged.

#### BFP Long Format

S	Exponent + 1023 (11 bits)	Fraction (52 bits)
0 1	12	31
Fraction (continued)		
32		63

Figure 19-2. BFP Long Format (8 bytes)

When an operand in the BFP long format is loaded into a floating-point register, it occupies the entire register.

#### BFP Extended Format

S	Exponent + 16383 (15 bits)	Fraction (112 bits)
0 1	16	31
Fraction (continued)		
32		63
Fraction (continued)		
64		95
Fraction (continued)		
96		127

Figure 19-3. BFP Extended Format (16 bytes)

An operand in the BFP extended format occupies a register pair. The sign and biased exponent are in the leftmost 16 bits of the lower-numbered register of the pair and are followed by the leftmost 48 bits of the fraction. The rightmost 64 bits of the fraction are in the higher-numbered register of the pair.

The properties of the three formats are tabulated in Figure 19-4 on page 19-3.

#### Biased Exponent

For each format, the bias that is used to allow all exponents to be expressed as unsigned numbers is shown in the Figure 19-4 on page 19-3. Biased exponents are similar to the characteristics of the HFP format, except that special meanings are attached to

Property	Format		
	Short	Long	Extended
Format length (bits)	32	64	128
Biased-exponent length (bits)	8	11	15
Fraction length (bits)	23	52	112
Precision (p)	24	53	113
Maximum left-units-view (LUV) exponent (Emax)	127	1023	16383
Minimum left-units-view (LUV) exponent (Emin)	-126	-1022	-16382
Left-units-view (LUV) bias	127	1023	16383
Nmax	$(1-2^{-24})x2^{128}$ $\approx 3.4 \times 10^{38}$	$(1-2^{-53})x2^{1024}$ $\approx 1.8 \times 10^{308}$	$(1-2^{-113})x2^{16384}$ $\approx 1.2 \times 10^{4932}$
Nmin	$1.0x2^{-126}$ $\approx 1.2 \times 10^{-38}$	$1.0x2^{-1022}$ $\approx 2.2 \times 10^{-308}$	$1.0x2^{-16382}$ $\approx 3.4 \times 10^{-4932}$
Dmin	$1.0x2^{-149}$ $\approx 1.4 \times 10^{-45}$	$1.0x2^{-1074}$ $\approx 4.9 \times 10^{-324}$	$1.0x2^{-16494}$ $\approx 6.5 \times 10^{-4966}$

**Explanation:**

≈ Value is approximate.

Dmin Smallest (in magnitude) representable subnormal number.

Nmax Largest (in magnitude) representable finite number.

Nmin Smallest (in magnitude) representable normal number.

Figure 19-4. Summary of BFP Data Formats

biased exponents of all zeros and all ones, which are discussed in the section “Classes of BFP Data” on page 19-4.

### Significand

In each format, the binary point of a BFP number is considered to be to the left of the leftmost fraction bit. To the left of the binary point there is an implied unit bit, which is considered to be one for normal numbers and zero for zeros and subnormal numbers. The fraction with the implied unit bit appended on the left is the *significand* of the number.

The value of a normal BFP number is the significand multiplied by the radix 2 raised to the power of the unbiased exponent. The value of a subnormal BFP number is the significand multiplied by the radix 2 raised to the power of the minimum exponent.

A value of one in the rightmost bit position of the significand in each format is sometimes referred to as one ulp (unit in the last place).

### Values of Nonzero Numbers

The values of nonzero numbers in the various formats are shown in Figure 19-5.

Number Class	Format	Value
Normal	Short	$\pm 2^{e-127}x(1.f)$
	Long	$\pm 2^{e-1023}x(1.f)$
	Extended	$\pm 2^{e-16383}x(1.f)$
Subnormal	Short	$\pm 2^{-126}x(0.f)$
	Long	$\pm 2^{-1022}x(0.f)$
	Extended	$\pm 2^{-16382}x(0.f)$

**Explanation:**

e Biased exponent (shown in decimal).  
f Fraction (in binary).

Figure 19-5. Values of Nonzero Numbers

**Programming Note:** ANSI/IEEE Standard 754-1985 specifies minimum requirements for the extended format but does not include details. The BFP extended format meets these requirements, far exceeding them in the area of precision.

## Classes of BFP Data

There are six classes of BFP data, which include numeric and related nonnumeric entities. Each data item consists of a sign, an exponent, and a significand. The exponent is biased such that all biased exponents are nonnegative unsigned numbers and the minimum biased exponent is zero. The significand consists of an explicit fraction and an implicit unit bit to the left of the binary point. The sign bit is zero for plus and one for minus.

All nonzero finite numbers permitted by a given format have a unique BFP representation. There are no unnormalized numbers, which numbers might allow multiple representations for the same values, and there are no unnormalized arithmetic operations. Tiny numbers of a magnitude below the minimum normal number in a given format are represented as *subnormal* numbers, but those values are also represented uniquely. The implied unit bit of a normal number is one, and that of a subnormal number or a zero is zero.

The six classes of BFP data are summarized in Figure 19-6 on page 19-4.

Data Class	Sign	Biased Exponent	Unit Bit*	Fraction
Zero	±	0	0	0
Subnormal numbers	±	0**	0	Not 0
Normal numbers	±	Not 0, not all ones	1	Any
Infinity	±	All ones	—	0
Quiet NaN	±	All ones	—	F0=1, Fr=any
Signaling NaN	±	All ones	—	F0=0, Fr≠0

**Explanation:**

— Does not apply.  
\* The unit bit is implied.  
\*\* The biased exponent is treated arithmetically as if it had the value one.  
F0 Leftmost bit of fraction.  
Fr Remaining bits of fraction.  
NaN Not-a-number.

Figure 19-6. Classes of BFP Data

The instruction TEST DATA CLASS may be used to determine the class of a BFP operand.

### Zeros

Zeros have a biased exponent of zero and a zero fraction. The implied unit bit is zero. A +0 is distinct from -0, except that comparison treats them as equal.

### Subnormal Numbers

Subnormal numbers are numbers which are smaller than the smallest normal number and greater than zero in magnitude. They have a biased exponent of zero and a nonzero fraction. The biased exponent is treated arithmetically as if it were one, which causes the exponent to be the minimum exponent. The implied unit bit is zero. (In ANSI/IEEE Standard 754-1985, subnormal numbers were called “denormalized numbers”.)

### Normal Numbers

Normal numbers have a biased exponent greater than zero but less than all ones. The implied unit bit is one, and the fraction may have any value. (In some early documentation, normal numbers were called “normalized numbers”.)

### Infinities

An infinity is represented by a biased exponent of all ones and a zero fraction. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. In comparisons,  $+\infty$  compares greater than any finite number, and  $-\infty$  compares less than any finite number.

### Signaling and Quiet NaNs

A NaN (not-a-number) entity is represented by a biased exponent of all ones and a nonzero fraction. NaNs are produced in place of a numeric result after an invalid operation when there is no interruption. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area.

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from the corresponding quiet NaN (QNaN) by the leftmost fraction bit: zero for the SNaN and one for the QNaN. A special QNaN is supplied as the default result for an IEEE-invalid-operation exception; it has a plus sign and a leftmost fraction bit of one, with the remaining fraction bits being set to zeros.

Normally, QNaNs are just propagated during computations so that they will remain visible at the end. An

SNaN operand causes an IEEE-invalid-operation exception. If the IEEE-invalid-operation mask (FPC 0.0) is zero, the result is the corresponding QNaN, which is produced by setting the leftmost fraction bit to one, and the IEEE-invalid-operation flag (FPC 1.0) is set to one. If the IEEE-invalid-operation mask (FPC 0.0) is one, the operation is suppressed, and a data exception for IEEE-invalid operation occurs.

### Programming Notes:

1. The program can generate and assign meanings to any nonzero fraction values of a NaN. The CPU propagates those values unchanged, except that an SNaN is changed to the corresponding QNaN if the IEEE-invalid-operation mask bit is zero, and conversion to a narrower format may truncate significant bits on the right.
2. ANSI/IEEE Standard 754-1985 requires SNaNs to signal the invalid-operation exception for the arithmetic, comparison, and conversion operations that are part of the standard, but it makes it an implementation option whether copying an SNaN without a change of format signals the exception. In the appendix, the standard also makes it an implementation option whether SNaNs should signal the invalid-operation exception for the recommended functions of copying the sign, taking the absolute value, reversing the sign, and testing the data class of a datum.

The above functions generally correspond to the instructions LOAD, LOAD COMPLEMENT, LOAD NEGATIVE, LOAD POSITIVE, and TEST DATA CLASS. These instructions do not signal the invalid-operation exception but, instead, treat SNaNs like any other data; giving an exception would be disruptive when the intention is to include SNaNs. TEST DATA CLASS does not give an exception since it is the instruction with which to test for the presence of SNaNs.

3. LOAD AND TEST signals the invalid-operation exception when the operand is an SNaN. This instruction, in conjunction with the above instructions, gives the program the choice of either option permitted by ANSI/IEEE Standard 754-1985.
4. Load-type instructions which change the precision signal the invalid-operation exception when the operand is an SNaN, as this is required by ANSI/IEEE Standard 754-1985.

## BFP-Format Conversion

BFP format conversion is described in the section “IEEE Same-Radix Format Conversion” on page 9-21.

## BFP Rounding

BFP rounding is described in the section “IEEE Rounding” on page 9-12.

## BFP Comparison

BFP comparison is described in the section “IEEE Comparison” on page 9-21.

## Remainder

The instruction DIVIDE TO INTEGER produces two floating-point results, an exact integer quotient and the corresponding remainder. The remainder is defined as follows:

Let

a = Dividend  
b = Divisor  
q = Exact quotient ( $a \div b$ )  
r = Remainder

in the selected floating-point format. Then

$$r = a - b \cdot n$$

where n is an integer. If q is an integer, then n equals q. Otherwise, n is obtained by rounding q according to a final-quotient-rounding method.

When the final-quotient-rounding method is round to nearest with ties to even or round toward zero, the remainder is exact for any finite dividend and any nonzero divisor. The remainder cannot overflow.

If the integer quotient has a value that lies outside the range of the operand format, a scaled result is provided.

In certain cases where the number of bits in the integer quotient exceeds or may exceed the maximum number of bits provided in the precision of the operand format, partial results are produced, and more

than one execution of the instruction is required to obtain the final result; this may be done with a simple instruction loop.

Partial results are produced when the precise quotient is not an integer and the two integers closest to this precise quotient cannot both be represented exactly in the precision of the quotient. This situation exists when the precise quotient is greater than  $2^P$ , where P is the precision of the operand format, and the remainder is not zero. When the remainder is zero, then the quotient is an integer, and the number of bits required to represent the quotient is never more than the precision of the target.

**Programming Note:** The remainder result of DIVIDE TO INTEGER with a final-quotient-rounding method of round to nearest with ties to even corresponds to the *Remainder* function in ANSI/IEEE Standard 754-1985. This function is similar to the *MOD* function found in some languages and to the mathematical

*modulo* function, but they are not the same. They differ in the definition of n:

Remainder	n is q rounded to nearest with ties to even.
modulo	n is q rounded toward $-\infty$ .
MOD	n is q rounded toward 0.

Another important difference is that implementations of modulo and MOD may put range restrictions on the result because they may simply use the DIVIDE instruction and accept its range restrictions.

The MOD definition provides an exact result, as does Remainder, but the modulo definition may result in rounding errors.

The differences between the various methods may be illustrated by the simple example of computing a divided by b to obtain an integer quotient n, where a is a series of integers, and b is +4 or -4. Figure 19-7 shows the results for the three definitions.

	a
	-8 -7 -6 -5 -4 -3 -2 -1 -0 +0 +1 +2 +3 +4 +5 +6 +7 +8
	Remainder
b=+4: n	-2 -2 -2 -1 -1 -1 -0 -0 -0 +0 +0 +0 +1 +1 +1 +2 +2 +2

r	0 -3 -2 -1 0 -3 -2 -1 0 -3 -2 -1 0 -3 -2 -1 0
<b>Explanation:</b>	
a	Dividend.
b	Divisor.
n	Integer quotient.
r	Result (Remainder, MOD, or modulo).

Figure 19-7. Comparison of Remainder with MOD and Modulo

The result of Remainder lies in the range of zero to one-half the divisor, inclusive, in magnitude. A zero

result is defined to have the sign of the dividend. A zero divisor is invalid.

The modulo and MOD results can both be computed from the Remainder result; the reverse may not be true, because of rounding errors and, depending on the implementation, range restrictions.

An extreme example of the rounding error that can occur with the modulo definition is the following, where the result is restricted to two significant decimal digits:

$\text{modulo}(0.01, -95) = -94.99$ , which rounds to -95

$\text{Remainder}(0.01, -95) = 0.01$

The properly rounded modulo result is completely wrong since it is equal to the divisor instead of being smaller in magnitude. The Remainder result is exact and can be used to compute the theoretical result of modulo.

Remainder is included as an arithmetic operation because of its usefulness in argument reduction when computing elementary transcendental functions. Thus,  $\text{SIN}(X)$  can be computed to full precision for any value of X in degrees by first reducing the argument to  $\text{Remainder}(X, 360)$ .

## IEEE Exceptions

The IEEE exceptions for the BFP instructions are described in the section "IEEE Exceptions" on page 9-16.

## Result Figures

Concise descriptions of the results produced by many of the BFP instructions are made by means of figures which contain columns and rows representing all possible combinations of BFP data class for the source operands of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross reference to another figure. In many cases, the information shown at the intersection consists of several symbols separated by commas. All such results are produced unless one of the results is

a program interruption. In the case of a program interruption, the operation is suppressed or completed as shown in Figure 19-9 on page 19-8.

## Data-Exception Codes (DXC) and Abbreviations

Figure 19-8 shows IEEE exceptions and flag abbreviations that are used in the result figures, and it explains the symbols "Xi:" and "Xz:" that are used in the figures. Bits 0-4 (i,z,o,u,x) of the eight-bit data-exception code (DXC) in byte 2 of the FPC register are trap flags and correspond to the same bits in bytes 0 and 1 of the register (IEEE masks and IEEE flags). The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit. Bit 5 of byte 2 (y) is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude.

Exception		FPC IEEE Mask Bit	IEEE Flag	
Name	Abbr.		FPC Bit	Abbr.
IEEE invalid operation	Xi <sup>1</sup>	0.0	1.0	SFi
IEEE division by zero	Xz <sup>2</sup>	0.1	1.1	SFz
IEEE overflow	Xo	0.2	1.2	SFo
IEEE underflow	Xu	0.3	1.3	SFu
IEEE inexact	Xx	0.4	1.4	SFx

### Explanation:

- 1 The symbol "Xi:" followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 80 hex, and a program interruption for a data exception occurs.
- 2 The symbol "Xz:" followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 40 hex, and a program interruption for a data exception occurs.

Figure 19-8. IEEE Exception and Flag Abbreviations

Figure 19-9 on page 19-8 shows the various DXCs that can be indicated, the associated instruction endings, and abbreviations that are used for the DXCs in

the result figures. (The abbreviation “PID” stands for “program interruption for a data exception.”)

<b>Abbr.</b>	<b>DXC (Hex)</b>	<b>Data-Exception-Code Name</b>	<b>Instruction Ending</b>
PIDx	08	IEEE inexact and truncated	Complete
PIDy	0C	IEEE inexact and incremented	Complete
PIDu	10	IEEE underflow, exact	Complete, scale exponent
PIDux	18	IEEE underflow, inexact and truncated	Complete, scale exponent
PIDuy	1C	IEEE underflow, inexact and incremented	Complete, scale exponent
PIDo	20	IEEE overflow, exact	Complete, scale exponent
PIDox	28	IEEE overflow, inexact and truncated	Complete, scale exponent
PIDoy	2C	IEEE overflow, inexact and incremented	Complete, scale exponent
PIDz	40	IEEE division by zero	Suppress
PIDI	80	IEEE invalid operation	Suppress

Figure 19-9. IEEE Data-Exception Codes (DXC) and Abbreviations

## Instructions

The BFP instructions and their mnemonics and operation codes are listed in Figure 19-10 on page 19-8.

The figure indicates, in the column labeled “Characteristics”, the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All BFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. For the BFP instructions to be executed successfully, the AFP-register-control bit must be one; otherwise, a BFP-instruction data exception, DXC 2, is recognized.

Mnemonics for the BFP instructions are distinguished from the corresponding HFP instructions by a B in the mnemonic. Mnemonics for the BFP instructions have an R as the last letter when the instruction is in the RRE or RRF format. Certain letters are used for BFP instructions to represent operand-format length, as follows:

- F Thirty-two-bit fixed point
- G Sixty-four-bit fixed point
- D Long
- E Short
- X Extended

**Note:** In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (short), for example, CEVR is the mnemonic and R<sub>1</sub>,R<sub>2</sub> the operand designation.

Mnemonic2 Op Code Operands  
 AEB 'ED0A' Short BFP  
 ADB 'ED1A' Long BFP

The second operand is added to the first operand, and the sum is placed at the first-operand location.

If both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode. The sum is then placed at the result location.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operands with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward  $-\infty$ , in which methods the sign is minus.
- The sign of the sum  $x$  plus  $x$  is the sign of  $x$ , even when  $x$  is zero.

If one operand is an infinity and the other is a finite number, the result is that infinity. If both operands are infinities of the same sign, the result is the same infinity. If the two operands are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

See Figure 19-12 on page 19-12 for a detailed description of the results of this instruction. (Figure 19-11 is referred to by Figure 19-12.)

For AXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

### Resulting Condition Code:

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 Result is a NaN

### IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

### Program Exceptions:

- Access (fetch, operand 2 of AEB and ADB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (AXBR only)

**Programming Note:** Interchanging the two operands in a BFP addition does not affect the value of the sum when the result is numeric. This is not true, however, when both operands are QNaNs, in which case the result is the first operand; or when both operands are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the first operand.

Value of Result (r)	Condition Code
r=0	cc0
r<0	cc1
r>0	cc2
<b>Explanation:</b>	
ccn	Condition code is set to n.

**Explanation:**

- \* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- ccn Condition code is set to n.
- ccrs Condition code is set according to the resultant sum. See Figure 19-11 on page 19-11.
- dNaN Default NaN.
- Dn Subnormal number.
- Nn Normal number.
- R(v) Rounding and range action is performed on the value v. See Figure 19-13 on page 19-13.
- Rezd Exact zero-difference result. See Figure 19-13 on page 19-13.
- T(x) The value x is placed at the target operand location.
- Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-12. Results: ADD

Range of v	Case	Nontrap Result (r) when Effective Rounding Method Is			
		To Nearest with ties to even	Toward 0	Toward +∞	Toward -∞

$+N_{\max} < v$ , $+N_{\max} < g$	Overflow	$+\infty^1$	$+N_{\max}$	$+\infty^1$	$+N_{\max}$

**Explanation:**

- This situation cannot occur.
- \* The rounded value, in the extreme case, may be Nmin. In this case, the exceptions are underflow, inexact and incremented.
- <sup>1</sup> The nontrap result r is considered to have been incremented.
- <sup>2</sup> The exact-zero-difference case applies only to ADD, SUBTRACT, MULTIPLY AND ADD, and MULTIPLY AND SUBTRACT. For all other BFP operations, a zero result is detected by inspection of the source operands without use of the R(v) function.

d The denormalized value. The value derived when the precise intermediate value (v) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note \*, this is a subnormal number.  
 g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.  
 v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For LOAD ROUNDED, v is the source value (a).  
 Dmin Smallest (in magnitude) representable subnormal number in the target format.  
 Nmax Largest (in magnitude) representable finite number in the target format.  
 Nmin Smallest (in magnitude) representable normal number in the target format.

Tiny	Yes	—	1	—	—	Yes	Yes	Tw(g÷Ψ), PIDuy(1C)

**Explanation:**

- The results do not depend on this condition or mask bit.
- <sup>1</sup> This condition is true by virtue of the state of some condition to the left of this column.
- Ψ Scale factor. For overflow,  $\Psi = 2^{+\alpha}$ . For underflow,  $\Psi = 2^{-\alpha}$ . The unsigned scaling exponent ( $\alpha$ ) depends on the type of operation and operand format. For all BFP operations except LOAD ROUNDED,  $\alpha$  depends on the target format and is 192 for short, 1536 for long, and 24576 for extended. For LOAD ROUNDED,  $\alpha$  depends on the source format, and is 512 for long and 8192 for extended.
- g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
- r Nontrap result as defined in Part 1 of this figure.
- v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.
- PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 19-9 on page 19-8.
- SFo IEEE overflow flag, FPC 1.2.
- SFu IEEE underflow flag, FPC 1.3.
- SFx IEEE inexact flag, FPC 1.4.
- T(x) The value x is placed at the target operand location.
- Tw(x) The scaled result x is placed at the target operand location. For all operations except BFP LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

Figure 19-13. Action for R(v): Rounding and Range Function (Part 2 of 2)

## COMPARE

Mnemonic1	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
Op Code		R <sub>1</sub> R <sub>2</sub>

Mnemonic1	Op Code	Operands
CEBR	'B309'	Short BFP
CDBR	'B319'	Long BFP
CXBR	'B349'	Extended BFP

Mnemonic2	R <sub>1</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXE]
Op Code	R <sub>1</sub> X <sub>2</sub> B <sub>2</sub> D <sub>2</sub>       Op Code	0 8 12 16 20 32 40 47

Mnemonic2	Op Code	Operands
CEB	'ED09'	Short BFP
CDB	'ED19'	Long BFP

The first operand is compared with the second operand, and the condition code is set to indicate the result.

If both operands are finite numbers, the comparison is algebraic and follows the procedure for BFP subtraction, except that the difference is discarded after setting the condition code, and both operands remain unchanged. If the difference is exactly zero with either sign, the operands are equal; this includes zero operands (so +0 equals -0). If a nonzero difference is positive or negative, the first operand is high or low, respectively.

+∞ compares greater than any finite number, and all finite numbers compare greater than -∞. Two infinity operands of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operands as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operands are QNaNs and neither operand is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operands are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interrupt

for a data exception with DXC 80 hex (IEEE invalid operation) occurs. If the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 19-14 on page 19-16 for a detailed description of the results of this instruction.

For CXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

### Resulting Condition Code:

- 0 Operands equal
- 1 First operand low
- 2 First operand high
- 3 Operands unordered

### IEEE Exceptions:

- Invalid operation

### Program Exceptions:

- Access (fetch, operand 2 of CEB and CDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (CXBR only)

### Programming Notes:

1. COMPARE may be used by a compiler to implement those comparisons which are required by ANSI/IEEE Standard 754-1985 to not recognize an exception when the result is unordered due to a QNaN.
2. ANSI/IEEE Standard 754-1985 requires that it be possible to compare BFP operands in different formats. To accomplish this, LOAD LENGTHENED may be used before COMPARE to convert the shorter operand to the same format as the longer.

First Operand (a) Is	Results for COMPARE (a:b) when Second Operand (b) Is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
-∞	cc0	cc1	cc1	cc1	cc1	cc1	cc3	Xi: cc3

0	16	24	28 31

Mnemonic1 Op Code Operands

KEBR	'B308'	Short BFP
KDBR	'B318'	Long BFP
KXBR	'B348'	Extended BFP

Mnemonic2 R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RXE]

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>		Op Code
0	8	12	16	20	32	40 47

Mnemonic2 Op Code Operands

KEB	'ED08'	Short BFP
KDB	'ED18'	Long BFP

The first operand is compared with the second operand, and the condition code is set to indicate the result. The operation is the same as for COMPARE

except that QNaN operands cause an IEEE-invalid-operation exception to be recognized. Thus, QNaN operands are treated as if they were SNaNs.

See Figure 19-16 on page 19-17 for a detailed description of the results of this instruction.

For KXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

### Resulting Condition Code:

- 0 Operands equal
- 1 First operand low
- 2 First operand high
- 3 Operands unordered

### IEEE Exceptions:

- Invalid operation

### Program Exceptions:

- Access (fetch, operand 2 of KEB and KDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (KXBR only)

### Programming Notes:

1. COMPARE AND SIGNAL may be used by a compiler to implement those comparisons which

are required by ANSI/IEEE Standard 754-1985 to recognize an exception when the result is unordered due to a QNaN.

- ANSI/IEEE Standard 754-1985 requires that it be possible to compare BFP operands in different

formats. To accomplish this, LOAD LENGTH-ENED may be used before COMPARE AND SIGNAL to convert the shorter operand to the same format as the longer.

First Operand (a) Is	Results for COMPARE AND SIGNAL (a:b) when Second Operand (b) Is						
	-∞	-Fn	-0	+0	+Fn	+∞	NaN
-∞	cc0	cc1	cc1	cc1	cc1	cc1	Xi: cc3

+Fn	cc2	cc2	cc2	cc2	C(a:b)	cc1	Xi: cc3
+∞	cc2	cc2	cc2	cc2	cc2	cc0	Xi: cc3
NaN	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3

**Explanation:**

ccn Condition code is set to n.  
C(a:b) Basic compare results. See Figure 19-15 on page 19-16  
Fn Finite nonzero number (includes both subnormal and normal).  
Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-16. Results: COMPARE AND SIGNAL

## CONVERT FROM FIXED

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
Op Code	R <sub>1</sub> R <sub>2</sub>	16 24 28 31

Mnemonic	Op Code	Operands
CEFBR	'B394'	32-bit binary-integer operand, short BFP result
CDFBR	'B395'	32-bit binary-integer operand, long BFP result
CXFBR	'B396'	32-bit binary-integer operand, extended BFP result
CEGBR	'B3A4'	64-bit binary-integer operand, short BFP result
CDGBR	'B3A5'	64-bit binary-integer operand, long BFP result
CXGBR	'B3A6'	64-bit binary-integer operand, extended BFP result

The fixed-point second operand is converted to the BFP format, and the result is placed at the first-operand location.

The second operand is a signed binary integer that is located in the general register designated by R<sub>2</sub>. A 32-bit operand is in bit positions 32-63 of the register.

The result is rounded according to the current BFP rounding mode before it is placed at the first-operand location.

See Figure 19-17 on page 19-18 for a detailed description of the results of this instruction.

For CXFBR and CXGBR, the R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### IEEE Exceptions:

- Inexact (CEFBR, CDGBR, CEGBR)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (CXFBR and CXGBR)

### Program Exceptions:

Instruction	Results for Instructions with a Single Operand (a) when Operand (a) Is							
	$-\infty$	-Fn	-0	+0	+Fn	$+\infty$	QNaN	SNaN
CONVERT FROM FIXED	—	Rf(a)	—	T(+0)	Rf(a)	—	—	—
LOAD AND TEST	T( $-\infty$ )	T(a)	T(-0)	T(+0)	T(a)	T( $+\infty$ )	T(a)	$Xi: T(a^*)$
LOAD LENGTHENED	T( $-\infty$ )	$T(a)^1$	T(-0)	T(+0)	$T(a)^1$	T( $+\infty$ )	$T(a)^1$	$Xi: T(a^*)^1$
LOAD ROUNDED	T( $-\infty$ )	R(a)	T(-0)	T(+0)	R(a)	T( $+\infty$ )	$T(a)^2$	$Xi: T(a^*)^2$
SQUARE ROOT	$Xi:$ T(dNaN)	$Xi:$ T(dNaN)	T(-0)	T(+0)	$R(\sqrt{a})$	T( $+\infty$ )	T(a)	$Xi: T(a^*)$

**Explanation:**

- This situation cannot occur.
- \* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- <sup>1</sup> The operand is extended to the longer format by appending zeros on the right before it is placed at the target operand location.
- <sup>2</sup> The NaN is shortened to the target format by truncating the rightmost bits.

dNaN Default NaN.  
Fn Finite nonzero number (includes both subnormal and normal).  
R(v) Rounding and range action is performed on the value v. See Figure 19-13 on page 19-14.  
Rf(a) The value a is converted to the precise intermediate value floating-point number v, and then action R(v) is performed.  
T(x) The value x is placed in the target operand location.  
Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-17. Results: Single-Operand Instructions

## CONVERT TO FIXED

Mnemonic R<sub>1</sub>,M<sub>3</sub>,R<sub>2</sub> [RRF]

Op Code	M <sub>3</sub>		R <sub>1</sub>	R <sub>2</sub>
0	16	20 24	28	31

Mnemonic	Op Code	Operands
CFEBR	'B398'	Short BFP operand, 32-bit binary-integer result
CFDBR	'B399'	Long BFP operand, 32-bit binary-integer result
CFXBR	'B39A'	Extended BFP operand, 32-bit binary-integer result
CGEBR	'B3A8'	Short BFP operand, 64-bit binary-integer result
CGDBR	'B3A9'	Long BFP operand, 64-bit binary-integer result
CGXBR	'B3AA'	Extended BFP operand, 64-bit binary-integer result

The BFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by R<sub>1</sub>. A 32-bit result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is a finite number, it is rounded to an integer value by rounding as specified by the modifier in the M<sub>3</sub> field:

### M<sub>3</sub> Effective Rounding Method

- 0 According to current BFP rounding mode
- 1 Round to nearest with ties away from 0
- 4 Round to nearest with ties to even
- 5 Round toward 0
- 6 Round toward  $+\infty$
- 7 Round toward  $-\infty$

A modifier other than 0, 1, or 4-7 is invalid.

When the modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode. Rounding for modifiers 4-7 is the same as for rounding methods 0-3 (binary 00-11), respectively. Round to nearest with ties away from 0 (modifier 1) is the same as round to nearest with ties to even (modifier 4), except when the second operand is exactly halfway between two integers, in which case the result for round to nearest with ties away from 0 is the next integer that is greater in magnitude.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

Operand (a)	Is n Inexact (n≠a)	Inv.-Op. Mask (FPC 0.0)	Inexact Mask (FPC 0.4)	Is n Incremented (Inl> al )	Results

#### Explanation:

– The results do not depend on this condition or mask bit.

<sup>1</sup> This condition is true by virtue of the state of some condition to the left of this column.

<sup>2</sup> The n=MP condition only applies to CFDBR, CFXBR, and CGXBR.

† Result differs from DFP CONVERT TO FIXED. The DFP instruction combines two cases as it does not recognize inexact for this case and does not test the inexact mask.

ccn Condition code is set to n.

f The value n converted to a fixed-point result.

n The value derived when the source value (a) is rounded to a floating-point integer using the effective rounding method.

MN Maximum negative number representable in the target fixed-point format.

MP Maximum positive number representable in the target fixed-point format.

PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. Figure 19-9 on page 19-8.

SFi IEEE invalid-operation flag, FPC 1.0.

SFx IEEE inexact flag, FPC 1.4.

T(x) The value x is placed at the target operand location.

Figure 19-18. Results: CONVERT TO FIXED

See Figure 19-18 for a detailed description of the results of this instruction.

The M<sub>3</sub> field must designate a valid modifier; otherwise, a specification exception is recognized. For

CFXBR and CGXBR, the R<sub>2</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

#### **Resulting Condition Code:**

- 0 Source was zero
- 1 Source was less than zero
- 2 Source was greater than zero
- 3 Special case

#### **IEEE Exceptions:**

- Invalid operation
- Inexact

#### **Program Exceptions:**

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification

DDB	'ED1D'	Long BFP

The first operand (the dividend) is divided by the second operand (the divisor), and the quotient is placed at the first-operand location. No remainder is preserved.

If the divisor is nonzero and both the dividend and divisor are finite numbers, the first operand is divided by the second operand to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format according to the current BFP rounding mode.

When the dividend is a finite number and the divisor is infinity, the result is zero.

The sign of the quotient, if the quotient is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite quotient.

If the divisor is zero but the dividend is a finite number, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinity, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 19-19 on page 19-21 for a detailed description of the results of this instruction.

For DXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### **IEEE Exceptions:**

- Invalid operation
- Division by zero
- Overflow
- Underflow
- Inexact

#### **Program Exceptions:**

**Explanation:**

- \* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- Fn Finite nonzero number (includes both subnormal and normal).
- R(v) Rounding and range action is performed on the value v. See Figure 19-13 on page 19-13.
- T(x) The value x is placed at the target operand location.
- Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
- Xz: IEEE division-by-zero exception. The results shown are produced only when FPC 0.1 is zero.

Figure 19-19. Results: DIVIDE

## DIVIDE TO INTEGER

Mnemonic	R <sub>1</sub> ,R <sub>3</sub> ,R <sub>2</sub> ,M <sub>4</sub>	[RRF]
Op Code	R <sub>3</sub> M <sub>4</sub> R <sub>1</sub> R <sub>2</sub>	16 20 24 28 31

Mnemonic	Op Code	Operands
DIEBR	'B353'	Short BFP
DIDBR	'B35B'	Long BFP

The first operand (the dividend) is divided by the second operand (the divisor). An integer quotient in BFP form is produced and placed at the third-operand location. The remainder replaces the dividend at the first-operand location. The first, second, and third operands must be in different registers. The condition code indicates whether partial or complete results have been produced and whether the quotient is a finite number.

The remainder result is

$$r = a - b \cdot n$$

where a is the dividend, b the divisor, and n an integer obtained by rounding the precise quotient

$$q = a \div b.$$

The first-operand result is r with the sign determined by the above expression. The third-operand result is

n with a sign that is the exclusive or of the dividend and divisor signs.

If the precise quotient is not an integer and the two integers closest to this precise quotient cannot both be represented exactly in the precision of the quotient, then a partial quotient and partial remainder are formed. This partial quotient n and the corresponding partial remainder

$$r = a - b \cdot n$$

are used as the results. The sign of a partial remainder is the same as the sign of the dividend. The sign of a partial quotient is the exclusive or of the dividend and divisor signs.

If the remainder is zero, then the precise quotient is an integer and can be represented exactly in the precision of the quotient.

The M<sub>4</sub> field, called the modifier field, specifies rounding of the final quotient. This rounding is called the “final-quotient-rounding method” as contrasted to the “current BFP rounding mode” specified by the BFP rounding-mode bits in the FPC register. The final quotient is rounded according to the final-quotient-rounding method. The final-quotient-rounding method affects only the final quotient; partial quotients are rounded toward zero.

Since the partial quotient is rounded toward zero, the partial remainder is always exact. For the final-quotient-rounding methods of round toward 0, round to nearest with ties to even, and round to nearest with ties away from 0, the final remainder is exact. For the final-quotient-rounding methods of round toward  $+\infty$  and round toward  $-\infty$ , the final remainder may not be exact.

The final quotient is rounded to an integer by rounding as specified by the modifier in the  $M_4$  field:

#### **$M_4$ Final-Quotient-Rounding Method**

- 0 According to current BFP rounding mode
- 1 Round to nearest with ties away from 0
- 4 Round to nearest with ties to even
- 5 Round toward 0
- 6 Round toward  $+\infty$
- 7 Round toward  $-\infty$

A modifier other than 0, 1, or 4-7 is invalid.

When the modifier field is zero, rounding of the final quotient is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode. Rounding for modifiers 4-7 is the same as for rounding modes 0-3 (binary 00-11), respectively. Round to nearest with ties away from 0 (modifier 1) is the same as round to nearest with ties to even (modifier 4), except when the final quotient is exactly halfway between two integers, in which case the result for round to nearest with ties away from 0 is the next integer that is greater in magnitude.

Underflow is recognized only on the final remainder, not on the partial remainder.

For the final-quotient-rounding methods of round toward  $+\infty$  and round toward  $-\infty$ , the final remainder may not be exact. When, in these cases, the final remainder is inexact, it is rounded according to the current BFP rounding mode specified in the FPC register.

The sign of a zero quotient is the exclusive or of the divisor and dividend signs.

A zero remainder has the sign of the dividend.

See Figure 19-20 on page 19-23 for a detailed description of the results of this instruction.

If the quotient exponent is greater than the largest exponent that can be represented in the operand format, the correct remainder or partial remainder still is produced, and the third-operand result is the correct value, but with the exponent reduced by 192 or 1536 for short or long operands, respectively. The condition code indicates this out-of-range condition.

The  $M_4$  field must designate a valid modifier, and the  $R_1$ ,  $R_2$ , and  $R_3$  fields must designate different registers; otherwise, a specification exception is recognized.

#### **Resulting Condition Code:**

- 0 Remainder complete; normal quotient
- 1 Remainder complete; quotient overflow or NaN
- 2 Remainder incomplete; normal quotient
- 3 Remainder incomplete; quotient overflow or NaN

#### **IEEE Exceptions:**

- Invalid operation
- Underflow
- Inexact

#### **Program Exceptions:**

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification

#### **Programming Notes:**

1. The Remainder operation, as defined in ANSI/IEEE Standard 754-1985, is produced by issuing DIVIDE TO INTEGER in an iterative loop, with the  $M_4$  field set to 4.
2. The rounding specifications of round to nearest with ties to even, round toward 0, and round toward  $-\infty$  permit the instruction to be used directly to produce the Remainder, MOD, and modulo functions, respectively.
3. When DIVIDE TO INTEGER is used in an iterative loop, all quotients are produced in BFP format but may be considered as portions of a multiple-precision fixed-point number.
4. In the case when the resulting remainder is subnormal, ANSI/IEEE Standard 754-1985 requires that if traps are implemented and the underflow mask is one, then an underflow trap must occur. To accomplish this, DIVIDE TO INTEGER recog-

No	No	Partial	— <sup>2</sup>	No <sup>1</sup>	—	—	No	—	T(r,n), cc2
No	No	Partial	— <sup>2</sup>	No <sup>1</sup>	—	—	Yes	—	T(r, n÷ $\Psi$ ), cc3

**Explanation:**

- The results do not depend on this condition or mask bit.

<sup>1</sup>This condition is true by virtue of the state of some condition to the left of this column. That is, when  $|q| < 2^P$ , there cannot be a quotient overflow; the cases of remainder is zero, tiny, or inexact are mutually exclusive; and when r is exact, it is not incremented.

<sup>2</sup>Underflow is not recognized for a partial remainder.

$\Psi$ Scale factor. For overflow,  $\Psi = 2^{+\alpha}$ . For underflow,  $\Psi = 2^{-\alpha}$ . The unsigned scaling exponent ( $\alpha$ ) depends on the operand format and is 512 for long and 8192 for extended.

$|q|$ The absolute value of q, where q is the precise intermediate value of a÷b before rounding, assuming unbounded precision and unbounded exponent range.

cc0Condition code is set to 0 (remainder complete; normal quotient).

cc1Condition code is set to 1 (remainder complete; quotient overflow).

cc2Condition code is set to 2 (remainder incomplete; normal quotient).

cc3Condition code is set to 3 (remainder incomplete; quotient overflow).

nInteger quotient. n = q, rounded toward 0 for partial results and rounded according to the final-quotient-rounding method for final results. The sign of the integer quotient, including the cases of partial and final, scaled value, and zero, is the exclusive or of the signs of the dividend (a) and divisor (b).

rRemainder. r = a-b•n. A partial remainder is always exact; no rounding is necessary. The sign of a partial remainder is always the same as the sign of the dividend (a). A final remainder is rounded according to the current BFP rounding mode (if necessary). The sign of a zero remainder is the same as the sign of the dividend (a). The sign of a nonzero final remainder is determined by the rules of algebra.

PPrecision of the operand, which depends on the target format: P = 24 for short and 53 for long.

PIDc(h)Program interruption for data exception, condition c, with DXC of h in hex. See Figure 19-9 on page 19-8.

SFiIEEE invalid-operation flag, FPC 1.0.

SFuIEEE underflow flag, FPC 1.3.

SFxIEEE inexact flag, FPC 1.4.

T(r,n)Results r (the remainder) and n (the integer quotient) are placed in target operands 1 and 3, respectively.

Figure 19-20. Results: DIVIDE TO INTEGER (Part 2 of 2)

**LOAD AND TEST**

LTXBR 'B342' Extended BFP

Mnemonic R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic Op Code Operands

LTEBR	'B302'	Short BFP
LTDBR	'B312'	Long BFP

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

The second operand is placed unchanged at the first-operand location. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN.

See Figure 19-17 on page 19-18 for a detailed description of the results of this instruction.

For LTXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### **Resulting Condition Code:**

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 Result is a NaN

#### **IEEE Exceptions:**

- Invalid operation

#### **Program Exceptions:**

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (LTXBR only)

**Programming Note:** LOAD AND TEST signals invalid operation when the operand is an SNaN. TEST DATA CLASS may be used to test an operand if signaling is not desired.

## **LOAD COMPLEMENT**

Mnemonic R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic	Op Code	Operands
LCEBR	'B303'	Short BFP
LCDBR	'B313'	Long BFP
LCXBR	'B343'	Extended BFP

The second operand is placed at the first-operand location with the sign bit inverted.

The sign bit is inverted even if the operand is zero. The rest of the second operand is placed unchanged at the first-operand location. The sign is inverted for

any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LCXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### **Resulting Condition Code:**

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 Result is a NaN

**IEEE Exceptions:** None.

#### **Program Exceptions:**

- Data with DXC 2, BFP instruction
- Specification (LCXBR only)

**Programming Note:** LOAD COMPLEMENT does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

## **LOAD FP INTEGER**

Mnemonic R<sub>1</sub>,M<sub>3</sub>,R<sub>2</sub> [RRF]

Op Code	M <sub>3</sub>		R <sub>1</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic	Op Code	Operands
FIEBR	'B357'	Short BFP
FIDBR	'B35F'	Long BFP
FIXBR	'B347'	Extended BFP

The second operand is rounded to an integer value in the same floating-point format, and the result is placed at the first-operand location.

The second operand, if a finite number, is rounded to an integer value as specified by the modifier in the M<sub>3</sub> field:

#### **M<sub>3</sub> Effective Rounding Method**

- 0 According to current BFP rounding mode
- 1 Round to nearest with ties away from 0
- 4 Round to nearest with ties to even
- 5 Round toward 0
- 6 Round toward +∞
- 7 Round toward -∞

A modifier other than 0, 1, or 4-7 is invalid.

When the modifier field is zero, rounding is controlled by the current BFP rounding mode in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode. Rounding for modifiers 4-7 is the same as for rounding modes 0-3 (binary 00-11), respectively. Round to nearest with ties away from 0 (modifier 1) is the same as round to nearest with ties to even (modifier 4), except when the second operand is exactly halfway between two integers, in which case the result for round to nearest with ties away from 0 is the next integer that is greater in magnitude.

In the absence of an interruption, if the second operand is an infinity or a QNaN, the result is that operand; if the second operand is an SNaN, the result is the corresponding QNaN.

The sign of the result is the sign of the second operand, even when the result is zero.

See Figure 19-21 on page 19-27 for a detailed description of the results of this instruction.

The  $M_3$  field must designate a valid modifier, and, for FIXBR, the R fields must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Invalid operation
- Inexact

**Program Exceptions:**

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification

**Programming Notes:**

1. LOAD FP INTEGER rounds a BFP number to an integer value. These integers, which remain in the BFP format, should not be confused with binary integers, which have a fixed-point format.
2. If the BFP operand is a finite number with a large enough exponent so that it is already an integer, the result value remains the same.

LXEGR	'ED06'	Short BFP operand 2, extended BFP operand 1

The second operand is converted to a longer format, and the result is placed at the first-operand location.

When the second operand is a finite number, the value of the second operand is placed in the target format. The exponent of the second operand is converted to the corresponding exponent in the result format, and the fraction is extended by appending zeros on the right.

If the second operand is an infinity, the result is an infinity of the same sign. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN with the fraction extended.

The sign of the result is the same as the sign of the source.

See Figure 19-17 on page 19-18 for a detailed description of the results of this instruction.

For LXDB, LXDBR, LXEB, and LXEBr, the R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### IEEE Exceptions:

- Invalid operation

#### Program Exceptions:

- Access (fetch, operand 2 of LDEB, LXEB, and LXDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (LXEB, LXEBr, LXDB, LXDBR)

## LOAD NEGATIVE

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]	
Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

#### Mnemonic Op Code Operands

LNEBR	'B301'	Short BFP
LNDBR	'B311'	Long BFP
LNXBR	'B341'	Extended BFP

The second operand is placed at the first-operand location with the sign bit made zero.

The sign bit is made one even if the operand is zero. The rest of the second operand is placed unchanged at the first-operand location. The sign is set for any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LNXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### Resulting Condition Code:

- 0 Result is zero
- 1 Result is less than zero
- 2 --
- 3 Result is a NaN

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (LNXBR only)

**Programming Note:** LOAD NEGATIVE does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

## LOAD POSITIVE

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]	
Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic	Op Code	Operands
LPEBR	'B300'	Short BFP
LPDBR	'B310'	Long BFP
LPXBR	'B340'	Extended BFP

The second operand is placed at the first-operand location with the sign bit made zero.

The sign bit is made zero, and the rest of the second operand is placed unchanged at the first-operand location. The sign is set for any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LPXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### Resulting Condition Code:

- 0 Result is zero
- 1 --
- 2 Result is greater than zero
- 3 Result is a NaN

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (LPXBR only)

**Programming Note:** LOAD POSITIVE does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

## LOAD ROUNDED

Mnemonic R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic	Op Code	Operands
LEDBR	'B344'	Long BFP source, short BFP target, short or long BFP result
LDXBR	'B345'	Extended BFP source, long BFP target, long or extended BFP result
LEXBR	'B346'	Extended BFP source, short BFP target, short or extended BFP result

The second operand, in the format of the source, is rounded to the precision of the target, and the result is placed at the first-operand location. The sign of the result is the same as the sign of the second operand.

The second operand, if a finite number, is rounded to the precision of the target fraction according to the current BFP rounding mode. In the absence of IEEE-trap action for overflow or underflow, the result is in the format and length of the target. However, when an IEEE overflow or an IEEE underflow is recognized and the corresponding mask bit is one, the operation is completed by producing a scaled result in the same format and length as the source but rounded to the precision of the target. A short-format result replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged. A long-format result is placed in a floating-point register, and the other register of the floating-point register pair, if any, remains unchanged. An extended-format result is placed in a floating-point register pair.

The sign of the result is the same as the sign of the second operand.

See Figure 19-17 on page 19-18 for a detailed description of the results of this instruction.

For LDXBR and LEXBR, the R<sub>1</sub> and R<sub>2</sub> fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

### Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (LDXBR and LEXBR)

### Programming Notes:

1. The sign of the rounded result is the same as the sign of the operand, even when the result is zero.
2. The R<sub>1</sub> field for LDXBR and LEXBR must designate a valid floating-point-register pair since in certain cases the result is in the extended format. In normal operation for LDXBR and LEXBR, the result format is long or short, respectively, and this result replaces the leftmost 32 bits or 64 bits of the target-register pair. However, when an IEEE overflow or an IEEE underflow is recognized and the corresponding mask bit is one, the operation is completed by placing a result in the extended format at the target location. Thus, the program must take into account the fact that these instructions sometimes update both registers of the pair.

## MULTIPLY

Mnemonic1 R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic1	Op Code	Operands
MEEBR	'B317'	Short BFP
MDBR	'B31C'	Long BFP
MXBR	'B34C'	Extended BFP
MDEBR	'B30C'	Short BFP multiplier and multiplicand, long BFP product
MXDBR	'B307'	Long BFP multiplier and multiplicand, extended BFP product

Mnemonic2	R <sub>1</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXE]				
Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>	/////////	Op Code
0	8	12	16	20	32	40

Mnemonic2	Op Code	Operands
MEEB	'ED17'	Short BFP
MDB	'ED1C'	Long BFP
MDEB	'ED0C'	Short BFP multiplier and multiplicand, long BFP product
MXDB	'ED07'	Long BFP multiplier and multiplicand, extended BFP product

The product of the second operand (the multiplier) and the first operand (the multiplicand) is placed at the first-operand location.

The two BFP operands, if finite numbers, are multiplied, forming an intermediate product. For MDEB, MDEBR, MXDB, and MXDBR, the intermediate product is converted to the longer target format; the result cannot overflow or underflow and is exact. For MDB, MDBR, MEEB, MEEBR, and MXBR, the result is rounded to the operand format according to the current BFP rounding mode. For MEEB and MEEBR, the result, as for all short-format results, replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged.

The sign of the product, if the product is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite product.

If one operand is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized.

See Figure 19-22 on page 19-31 for a detailed description of the results of this instruction.

The R<sub>1</sub> field for MXDB, MXDBR, and MXBR, and the R<sub>2</sub> field for MXBR, must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### **IEEE Exceptions:**

- Invalid operation
- Overflow (MDB, MDBR, MEEB, MEEBR, MXBR)
- Underflow (MDB, MDBR, MEEB, MEEBR, MXBR)
- Inexact (MDB, MDBR, MEEB, MEEBR, MXBR)

#### **Program Exceptions:**

- Access (fetch, operand 2 of MDEB, MEEB, MDB, and MXDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (MXDB, MXDBR, MXBR)

**Programming Note:** Interchanging the two operands in a BFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operands are QNaNs, in which case the result is the first operand; or when both operands are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the first operand.

First Operand (a) Is	Results for MULTIPLY (a•b) when Second Operand (b) Is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
-∞	T(+∞)	T(+∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(-∞)	T(-∞)	T(b)	Xi: T(b*)
-Fn	T(+∞)	R(a•b)	T(+0)	T(-0)	R(a•b)	T(-∞)	T(b)	Xi: T(b*)
-0	Xi: T(dNaN)	T(+0)	T(+0)	T(-0)	T(-0)	Xi: T(dNaN)	T(b)	Xi: T(b*)
+0	Xi: T(dNaN)	T(-0)	T(-0)	T(+0)	T(+0)	Xi: T(dNaN)	T(b)	Xi: T(b*)
+Fn	T(-∞)	R(a•b)	T(-0)	T(+0)	R(a•b)	T(+∞)	T(b)	Xi: T(b*)
+∞	T(-∞)	T(-∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(+∞)	T(+∞)	T(b)	Xi: T(b*)
QNaN	T(a)	T(a)	T(a)	T(a)	T(a)	T(a)	T(a)	Xi: T(b*)
SNaN	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)

**Explanation:**

- \* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- dNaN Default NaN.
- Fn Finite nonzero number (includes both subnormal and normal).
- R(v) Rounding and range action is performed on the value v. See Figure 19-13 on page 19-13.
- T(x) The value x is placed at the target operand location.
- Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-22. Results: MULTIPLY

## MULTIPLY AND ADD

Mnemonic1 R <sub>1</sub> ,R <sub>3</sub> ,R <sub>2</sub> [RRF]				
Op Code	R <sub>1</sub>	///	R <sub>3</sub>	R <sub>2</sub>

Mnemonic2	Op Code	Operands
MSEB	'ED0F'	Short BFP
MSDB	'ED1F'	Long BFP

The third operand is multiplied by the second operand, and then the first operand is added to or subtracted from the product. The sum or difference is placed at the first-operand location. The MULTIPLY AND ADD and MULTIPLY AND SUBTRACT operations may be summarized as:

$$\text{op}_1 = \text{op}_3 \cdot \text{op}_2 \pm \text{op}_1$$

When the operands are finite numbers, the third and second BFP operands are multiplied, forming an intermediate product, and the first operand is then added (or subtracted) algebraically to (or from) the intermediate product, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode and then placed at the first-operand location. The exponent and fraction of the intermediate product are maintained exactly; rounding and range checking occur only on the intermediate sum.

Third Operand (a) Is	Results, Part 1, for MULTIPLY AND ADD (a•b+c) when Second Operand (b) Is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN

-0	T(-∞)	R(c)	T(-0)	Rezd	R(c)	T(+∞)	T(c)	Xi: T(c*)
+0	T(-∞)	R(c)	Rezd	T(+0)	R(c)	T(+∞)	T(c)	Xi: T(c*)
+Fn	T(-∞)	R(p+c)	R(p)	R(p)	R(p+c)	T(+∞)	T(c)	Xi: T(c*)
+∞	Xi: T(dNaN)	T(+∞)	T(+∞)	T(+∞)	T(+∞)	T(+∞)	T(c)	Xi: T(c*)
QNaN	T(p)	T(p)	T(p)	T(p)	T(p)	T(p)	T(p)	Xi: T(c*)

**Explanation:**

- \* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- dNaN Default NaN.
- Fn Finite nonzero number (includes both subnormal and normal).
- P(x) The value x is passed to Part 2 of this figure.
- R(v) Rounding and range action is performed on the value v. See Figure 19-13 on page 19-13.
- Rezd Exact zero-difference result. See Figure 19-13 on page 19-13.
- T(x) The value x is placed at the target operand location.
- Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-23. Results: MULTIPLY AND ADD (Part 2 of 2)

See Figure 19-23 for a detailed description of the results of MULTIPLY AND ADD. The results of MULTIPLY AND SUBTRACT are the same, except that the first operand, if numeric, participates in the operation with its sign bit inverted. When the first operand is a NaN, it participates in the operation with its sign bit unchanged.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Invalid operation
- Overflow
- Underflow
- Inexact

**Program Exceptions:**

- Access (fetch, operand 2 of MAEB, MADB, MSEB, MSDB)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception

**Programming Note:** MULTIPLY AND ADD and MULTIPLY AND SUBTRACT produce a precise intermediate value, and a single rounding operation is performed after the addition or subtraction. This definition is consistent with the Power architecture, and, in certain applications, can be used to great advantage, especially in algorithms used in math libraries.

## SQUARE ROOT

Mnemonic1	R <sub>1</sub> ,R <sub>2</sub>	[RRE]		
Op Code		R <sub>1</sub>	R <sub>2</sub>	
0	16	24	28	31

Mnemonic1	Op Code	Operands
SQEBR	'B314'	Short BFP
SQDBR	'B315'	Long BFP
SQXBR	'B316'	Extended BFP

Mnemonic2	R <sub>1</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXE]					
Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>		Op Code	
0	8	12	16	20	32	40	47

Mnemonic2	Op Code	Operands
SQEB	'ED14'	Short BFP
SQDB	'ED15'	Long BFP

The square root of the second operand is placed at the first-operand location.

The result rounded according to the current BFP rounding mode is placed at the first-operand location.

If the second operand is a positive finite number, the result is the square root of that number with a plus sign. If the operand is a zero of either sign, the result is a zero of the same sign. If the operand is  $+\infty$ , the result is  $+\infty$ .

If the second operand is less than zero, an IEEE-invalid-operation exception is recognized.

See Figure 19-17 on page 19-18 for a detailed description of the results of this instruction.

For SQXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### IEEE Exceptions:

- Invalid operation
- Inexact

### Program Exceptions:

- Access (fetch, operand 2 of SQEB and SQDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (SQXBR only)

## SUBTRACT

Mnemonic1	R <sub>1</sub> ,R <sub>2</sub>	[RRE]		
Op Code		R <sub>1</sub>	R <sub>2</sub>	
0	16	24	28	31

Mnemonic1	Op Code	Operands
SEBR	'B30B'	Short BFP
SDBR	'B31B'	Long BFP
SXBR	'B34B'	Extended BFP

Mnemonic2	R <sub>1</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXE]					
Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>		Op Code	
0	8	12	16	20	32	40	47

Mnemonic2	Op Code	Operands
SEB	'ED0B'	Short BFP
SDB	'ED1B'	Long BFP

The second operand is subtracted from the first operand, and the difference is placed at the first-operand location.

The execution of SUBTRACT is identical to that of ADD, except that the second operand, if numeric, participates in the operation with its sign bit inverted. When the second operand is a NaN, it participates in the operation with its sign bit unchanged. See Figure 19-12 on page 19-12 for the detailed results of ADD.

For SXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

### Resulting Condition Code:

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 Result is a NaN

### IEEE Exceptions:

- Invalid operation

- Overflow
- Underflow
- Inexact

**Program Exceptions:**

- Access (fetch, operand 2 of SEB and SDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (SXBR only)

## TEST DATA CLASS

Mnemonic	R <sub>1</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXE]
Op Code	R <sub>1</sub> X <sub>2</sub> B <sub>2</sub> D <sub>2</sub> ////////////// Op Code	0 8 12 16 20 32 40 47

Mnemonic	Op Code	Operands
TCEB	'ED10'	Short BFP
TCDB	'ED11'	Long BFP
TCXB	'ED12'	Extended BFP

The class and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of BFP data class and sign. Bits 0-51 of the second-operand address are ignored.

As shown in Figure 19-24, BFP operands are divided into six classes: zero, normal number, subnormal number, infinity, quiet NaN, and signaling NaN.

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the class and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

BFP Operand Class	Bit Used when Sign Is	
	+	-
Zero	52	53
Normal number	54	55
Subnormal number	56	57
Infinity	58	59
Quiet NaN	60	61
Signaling NaN	62	63

Figure 19-24. Second-Operand-Address Bits for TEST DATA CLASS

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TCXB, the R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Resulting Condition Code:**

- 0 Selected bit is 0 (no match)
- 1 Selected bit is 1 (match)
- 2 --
- 3 --

**IEEE Exceptions:** None.

**Program Exceptions:**

- Data with DXC 2, BFP instruction
- Specification (TCXB only)

**Programming Notes:**

1. TEST DATA CLASS provides a way to test an operand without risk of an exception or setting the IEEE flags.
2. The bits used to specify the combinations of data class and sign are not all the same for BFP and DFP. Specifically, DFP TEST DATA CLASS uses bits 54 and 55 for subnormal number, and bits 56 and 57 for normal number.

## Decimal-Floating-Point Facility

The decimal-floating-point (DFP) facility provides instructions to operate on decimal (radix-10) floating-point data. The facility was designed in cooperation with the IEEE floating-point working group.

Additionally, this facility was designed to support a common library for various systems. This facility in both the z/architecture and Power architectures sup-

ports the same data formats, the same rounding methods, the same functions, and the same exceptions.

DFP has a number of important characteristics:

- It produces results consistent with decimal arithmetic as taught in elementary school.
- It recognizes the quantum of a finite number, maintains quantum information through arithmetic operations, and provides special opera-

tions to extract, compare, and adjust the quantum.

- It provides greater exponent range than hexadecimal-floating-point (HFP) and binary-floating-point (BFP) while maintaining comparable precision.
- It provides greater precision and better space efficiency than provided by the decimal-arithmetic instructions and the packed-decimal format as described in Chapter 8, “Decimal Instructions.”
- It supports IEEE flags, exceptions, and special entities of “infinity” and “Not-a-Number” (NaN).
- It supports eight automatic rounding methods.
- It facilitates production of DFP results with a precision other than any supported format precision and with the effect of single rounding.
- It provides operations for conversion between fixed-point and DFP formats.
- It provides operations for conversion between packed-decimal and DFP formats.
- It provides three-operand nondestructive arithmetic operations by permitting different target-operand registers from source-operand registers.

The DFP facility uses the same 16 floating-point registers as those used by HFP and BFP. A set of radix-independent floating-point-support instructions can be used to load, store, or change the sign of a DFP operand. These instructions are defined in Chapter 9, “Floating-Point Overview and Support Instructions.”

The DFP facility uses the same floating-point-control (FPC) register as that used by BFP. The bits of the FPC register are often referred to as, for example, FPC1.0, meaning bit 0 of byte 1 of the register. The description of the FPC register, including the DFP-rounding-mode field, and the instructions that operate on the FPC register are provided in Chapter 9, “Floating-Point Overview and Support Instructions.”

The DFP computational model, a high-level overview of the computational steps, is described in the section “IEEE Computational Operations” of Chapter 9, “Floating-Point Overview and Support Instructions.” Detailed definitions of rounding methods and IEEE

exceptions supported by DFP are also described in the section.

---

## DFP Arithmetic

### Finite Floating-Point Number

A finite floating-point number has three components: a sign, an exponent, and a significand. The magnitude of a finite number is the product of significand multiplied by the radix raised to the power of the exponent. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

#### Cohort

Finite decimal-floating-point (DFP) numbers are not necessarily normalized; that is, the leftmost significand digit may be zero. This allows some values to have multiple representations; each with a different combination of the significand and the exponent. The set of different representations for a value of the same sign is called a cohort; and each representation in a cohort is called a cohort member. A plus zero and a minus zero have the same value but are in different cohorts.

#### Quantum

For a DFP finite number, the magnitude of a value of one in the rightmost digit position of the significand is called the quantum. Each cohort member of a cohort uses a different quantum to represent the same value. The quantum of a cohort member is the same, regardless of whether the left-units view or right-units view is taken.

#### Preferred Quantum

For operations that produce a DFP result, when, in the absence of a trap overflow or a trap underflow, the delivered value is a finite number, a value, called the preferred quantum, is defined to select a cohort member to represent the delivered value. The preferred quantum for each of these operations is shown in Figure 20-4 on page 20-9. When the delivered value is exact, the preferred quantum depends on the operation. When the delivered value is inexact, the preferred quantum is the smallest quantum of the cohort members, unless otherwise stated.

## Scaled Preferred Quantum

For operations that produce a DFP result, when a trap overflow or a trap underflow occurs, a scaled preferred quantum is used to select a cohort member to represent the delivered value. The scaled preferred quantum is obtained by scaling the preferred quantum using the same scale factor as that used to obtain the delivered value.

## Delivered Quantum

Normally, when the delivered value is a finite number, the result is selected from the cohort for the delivered value in the target format. However, in case of a trap overflow or trap underflow for LOAD ROUNDED, the result is selected from a subset of the cohort for the delivered value in the source format. This subset of the cohort consists of cohort members that have the number of DFP significand digits equal to or less than the precision of the target format.

In the absence of a trap overflow or trap underflow, if the delivered value is a finite number, the cohort member with the quantum closest to the preferred quantum is selected.

In case of a trap overflow or trap underflow, the cohort member with the quantum closest to the scaled preferred quantum is selected.

## Special Quantum-Handling Operations

Special operations are provided to handle the quantum: COMPARE BIASED EXPONENT can be used to compare two quanta; EXTRACT BIASED EXPONENT can be used to determine the quantum of a finite number; and QUANTIZE can be used to adjust the quantum of a finite number.

### Programming Notes:

1. Many financial applications and commercial databases use scaled integer representation of decimal data. Calculations are carried out by using integer arithmetic and scaling factors are tracked separately; the scaling factor is often an attribute of a column in the database.

This computational model can be supported by DFP by allowing the integer part of decimal data

to map into the significand with a right-units view and the scaling factor to map into the quantum.

2. The term coefficient is used in some other documents to mean an integer value in significand; that is, significand in right-units view.

## DFP Data Formats

Decimal-floating-point data may be represented in any of three data formats: short, long, or extended.

The contents of each data format represent encoded information. Special codes are assigned to distinguish finite numbers from NaNs and infinities.

For finite numbers, a biased exponent is used in the format. For each format, a different bias is used for right-units-view (RUV) exponents from that for left-units-view (LUV) exponents. The biased exponents are unsigned numbers and all biases are shown in the Figure 20-3 on page 20-6. The biased exponent is encoded with the leftmost digit (LMD) of the significand in the combination field. The remaining digits of the significand are encoded in the encoded trailing-significand field.

### DFP Short Format

S	Combination	Encoded Trailing Significand	
0 1		12	31

When an operand in the DFP short format is loaded into a floating-point register, it occupies the left half of the register, and the right half remains unchanged.

### DFP Long Format

S	Combination	Encoded Trailing Significand	
0 1		14	31
Encoded Trailing Significand (continued)			
32			63

When an operand in the DFP long format is loaded into a floating-point register, it occupies the entire register.

## DFP Extended Format

S	Combination	Encoded Trailing Significand
0	18	31
Encoded Trailing Significand (continued)		63
32	63	
Encoded Trailing Significand (continued)		95
64	95	
Encoded Trailing Significand (continued)		127
96		

An operand in the DFP extended format occupies a register pair. The leftmost 64 bits occupy the entire lower-numbered register of the pair and the rightmost 64 bits occupy the entire higher-numbered register.

The properties of the three formats are tabulated in Figure 20-3 on page 20-6.

### Sign

The sign bit is in bit 0 of each format, and is zero for plus and one for minus.

### Combination

For finite numbers, this field contains the biased exponent and the leftmost digit of the significand; for NaNs and infinities, this field contains codes to identify them.

When bits 1-5 of the format are in the range of 00000 - 11101, the operand is a finite number. The two leftmost bits of the biased exponent and the leftmost digit of the significand are encoded in bits 1-5 of the format. Bit 6 through the end of the combination field contain the rest of the biased exponent.

When bits 1-5 of the format field are 11110, the operand is an infinity. All bits in the combination field to the right of bit 5 of the format constitute the reserved field for infinity. A nonzero value in the reserved field is accepted in a source infinity; the reserved field is set to zero in a resultant infinity.

When bits 1-5 of the format are 11111, the operand is a NaN and bit 6, called the SNaN bit, further distinguishes QNaN from SNaN. If bit 6 is zero, then it is QNaN; otherwise, it is SNaN. All bits in the combination field to the right of bit 6 of the format constitute the reserved field for NaN. A nonzero value in the reserved field is accepted in a source NaN; the reserved field is set to zero in a resultant NaN.

Figure 20-1 summarizes the encoding and layout of the combination field. In the figure, the biased exponent of a finite number is the concatenation of two parts: (1) two leftmost bits are derived from bits 1-5 of the format, and (2) the remaining bits in the combination field. For example, if the combination field of the DFP short format contains 101010101 binary, it represents a biased exponent of 10010101 binary and a leftmost significand digit of 5.

Bits 1 2 3 4 5	Bit 6	Type	Biased Exponent	LMD
00000	m	Finite number	00   RBE	0
00001	m	Finite number	00   RBE	1

11101	m	Finite number	10   RBE	9
11110	r	Infinity <sup>1</sup>	--	--
11111	0	QNaN <sup>2</sup>	--	--

Figure 20-1. The Combination Field

Bits 1 2 3 4 5	Bit 6	Type	Biased Exponent	LMD
11111	1	SNaN <sup>2</sup>	--	--

**Explanation:**

- Not applicable.
- | Concatenation.
- <sup>1</sup> All bits in the combination field to the right of bit 5 of the format constitute the reserved field for infinity.
- <sup>2</sup> All bits in the combination field to the right of bit 6 of the format constitute the reserved field for NaN.
- LMD Leftmost digit of the significand.
- m Bit 6 is a part of the remaining biased exponent.
- RBE Remaining biased exponent. It includes all bits in the combination field to the right of bit 5 of the format.
- r Bit 6 is a reserved bit for infinity.

Figure 20-1. The Combination Field (Continued)

### Encoded Trailing Significand

This field contains an encoded decimal number, which represents digits in the trailing significand. The trailing significand contains all significand digits, except the leftmost digit. For infinities, nonzero trailing-significand digits are accepted in a source infinity; all trailing-significand digits in a resultant infinity are set to zeros, unless otherwise stated. For NaNs, this field contains diagnostic information called the payload.

The encoded trailing-significand field is a multiple of 10-bit blocks called declets. The number of declets depends on the format. Each declet represents three decimal digits in a 10-bit value. This is described in the section, “Densely Packed Decimal (DPD)” on page 20-42.

### Values of Finite Numbers

The values of finite numbers in the various formats are shown in Figure 20-2.

Format	Value	
	Left-Units View	Right-Units View
Short	$\pm 10^{e-95} \times (d_0.d_1d_2...d_6)$	$\pm 10^{e-101} \times (d_0d_1d_2...d_6)$
Long	$\pm 10^{e-383} \times (d_0.d_1d_2...d_{15})$	$\pm 10^{e-398} \times (d_0d_1d_2...d_{15})$
Extended	$\pm 10^{e-6143} \times (d_0.d_1d_2...d_{33})$	$\pm 10^{e-6176} \times (d_0d_1d_2...d_{33})$

**Explanation:**

- $d_0.d_1d_2...d_{p-1}$  Significand in left-units view. The decimal point is to the immediate right of the leftmost digit and  $d_i$  is a decimal digit, where  $0 \leq i \leq (p - 1)$  and  $p$  is the format precision.
- $d_0d_1d_2...d_{p-1}$  Significand in right-units view. The decimal point is to the right of the rightmost digit and  $d_i$  is a decimal digit, where  $0 \leq i \leq (p - 1)$  and  $p$  is the format precision.
- e Biased exponent.

Figure 20-2. Values of Finite Numbers

**Programming Note:** The RUV exponent, Q, is related to the LUV exponent, E, as follows:  $Q = E - p + 1$ , where  $p$  is the format precision.

### Significand

Hereafter, the term significand is used to mean the following:

1. For finite numbers, the significand contains all trailing significand digits padded on the left with the leftmost digit of significand derived from the combination field.
2. For infinities and NaNs, the significand contains all trailing significand digits padded on the left with a zero digit.

### DFP Significant Digits

For a finite number, the DFP significant digits begin with the leftmost nonzero significand digit and end with the rightmost significand digit.

For a finite number, the number of DFP significant digits is the difference of subtracting the number of leading zeros from the format precision. The number of leading zeros is the number of zeros in the significand to the left of the leftmost nonzero digit.

**Programming Note:** The number of DFP significant digits of the value zero is zero.

Property	Format		
	Short	Long	Extended
Format length (bits)	32	64	128
Combination length (bits)	11	13	17
Encoded Trailing significand length (bits)	20	50	110
Precision (p)	7	16	34
Maximum left-units-view (LUV) exponent (Emax)	96	384	6144
Minimum left-units-view (LUV) exponent (Emin)	-95	-383	-6143
Left-units-view (LUV) bias	95	383	6143
Maximum right-units-view (RUV) exponent (Qmax)	90	369	6111
Minimum right-units-view (RUV) exponent (Qmin)	-101	-398	-6176
Right-units-view (RUV) bias	101	398	6176
Maximum biased exponent	191	767	12,287
Nmax	$(10^7 - 1) \times 10^{90}$	$(10^{16} - 1) \times 10^{369}$	$(10^{34} - 1) \times 10^{6111}$
Nmin	$1 \times 10^{-95}$	$1 \times 10^{-383}$	$1 \times 10^{-6143}$
Dmin	$1 \times 10^{-101}$	$1 \times 10^{-398}$	$1 \times 10^{-6176}$

**Explanation:**

Dmin      Smallest (in magnitude) subnormal number.  
Nmax      Largest (in magnitude) normal number.  
Nmin      Smallest (in magnitude) normal number,

Figure 20-3. Summary of DFP Formats

## Canonical Declets

The trailing significand digits in a DFP data format are encoded by representing three decimal digits with a 10-bit declet. Of the 1024 possible declets, 1000 canonical declets are produced in resultant DFP operands, and 24 noncanonical declets are not produced as DFP results. Both canonical and noncanonical declets are accepted in source DFP operands. The encoding of a canonical declet or noncanonical declet is described in the section, “Densely Packed Decimal (DPD)” on page 20-42.

## DFP Canonical Data

A finite number is canonical when all declets are canonical declets.

An infinity is canonical when the reserved field is zero and all digits in the trailing significand are zeros.

A NaN is canonical when the reserved field is zero and all declets are canonical declets.

**Programming Note:** To ensure compatibility with future extensions and interchangeability between software routines, only DFP canonical data should be used.

## Classes of DFP Data

There are six classes of DFP data: zero, subnormal number, normal number, infinity, signaling NaN, and quiet NaN. The zero, subnormal number, and normal number data classes are collectively called finite numbers. The instruction TEST DATA CLASS may be used to determine the class of a DFP operand.

### Zeros

Zeros have a zero significand and any representable value in the biased exponent. A +0 is distinct from a -0 and zeros with different biased exponents are distinct, except that comparison treats them as equal.

### Subnormal Numbers

Subnormal numbers are numbers which are smaller than Nmin and larger than zero in magnitude.

## Normal Numbers

Normal numbers are numbers whose magnitude is between Nmin and Nmax inclusively.

## Infinities

An infinity is represented by 11110 binary in bits 1-5 of the data format. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. In comparisons,  $+\infty$  compares greater than any finite number, and  $-\infty$  compares less than any finite number. All  $+\infty$  are compared equal and all  $-\infty$  are compared equal.

## Signaling and Quiet NaNs

A NaN (Not-a-Number) is represented by 11111 binary in bits 1-5 of the data format. NaNs are produced in place of a numeric result after an invalid operation when there is no interruption. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area.

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from a quiet NaN (QNaN) by bit 6, the SNaN bit, of the data format: zero for the QNaN and one for the SNaN. A special QNaN, called the default QNaN, is supplied as the nontrap result for an IEEE-invalid-operation exception; it has a plus sign, and the SNaN bit, the reserved field, and the payload are set to zeros.

Normally, source QNaNs are canonicalized to become the resultant QNaN that has the same sign and payload as the source during operations so that they will remain visible at the end. (See the section “Canonicalization” on page 20-7 for details.) An SNaN operand causes an IEEE invalid-operation exception, unless otherwise stated. When the exception is recognized for a SNaN, the nontrap result is the corresponding QNaN, which is produced by setting the SNaN bit in the source SNaN to zero and then the converted QNaN is canonicalized, and the IEEE-invalid-operation flag (FPC 1.0) is set to one.

## Canonicalization

For operations that are defined to produce a DFP result, the result placed at the target operand location is canonical, unless otherwise stated.

## Programming Notes:

1. The following instructions may produce a noncanonical infinity as the result:

- INSERT BIASED EXPONENT
- LOAD LENGTHENED
- LOAD ROUNDED
- SHIFT SIGNIFICAND LEFT
- SHIFT SIGNIFICAND RIGHT

Infinities produced as a DFP result have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. However, the infinity produced by the above instructions does not necessarily have zeros in all digits in the trailing significand. Such an infinity is not canonical.

2. Only canonical operands should be used, as it is possible that some libraries or software routines reject noncanonical operands.
3. Except for INSERT BIASED EXPONENT, if only canonical source operands are used, the result is canonical. INSERT BIASED EXPONENT may produce a noncanonical result even if all source operands are canonical. Special precautions should be taken to avoid producing a noncanonical result from INSERT BIASED EXPONENT.

## DFP-Format Conversion

DFP format conversion is described in the section “IEEE Same-Radix Format Conversion” of Chapter 9, “Floating-Point Overview and Support Instructions.”

## DFP Rounding

DFP rounding is described in the section “IEEE DFP Rounding” of Chapter 9, “Floating-Point Overview and Support Instructions.”

## DFP Comparison

DFP comparison is described in the section “IEEE Comparison” of Chapter 9, “Floating-Point Overview and Support Instructions.”

## DFP Formatting Instructions

A set of instructions are provided to compose and decompose DFP data. These instructions do not recognize any IEEE exceptions. They are:

- CONVERT FROM SIGNED PACKED

- CONVERT FROM UNSIGNED PACKED
- CONVERT TO SIGNED PACKED
- CONVERT TO UNSIGNED PACKED
- EXTRACT BIASED EXPONENT
- INSERT BIASED EXPONENT
- SHIFT SIGNIFICAND LEFT
- SHIFT SIGNIFICAND RIGHT

Conversion of data between character strings in an external format and the DFP format may be performed in several steps. At certain steps, for finite numbers, the significand is kept in the packed-decimal format and the biased exponent in the fixed-point format. See Chapter 8, “Decimal Instructions,” for a detailed description of the packed-decimal format.

It takes 17 digits to hold the 16 significand digits and one sign of a long DFP format; it takes 35 digits for an extended DFP format. To facilitate the conversion, the significand is divided into pieces and only one piece contains the sign. Each piece fits into a register or a register pair, and each piece is converted separately. To support this piecemeal conversion, two formats, signed-packed-decimal and unsigned-packed-decimal, are used to hold the pieces.

### Signed-Packed-Decimal Format

In the signed-packed-decimal format, each byte contains two 4-bit decimal digits (D), except for the rightmost byte, which contains a 4-bit sign (S) to the right of a 4-bit decimal digit.

When a signed-packed-decimal operand resides in a general register (GR), the operand is 64 bits (15 digits and sign), as shown below.

GR	D   D   D   D   D   D   D   D   D   D   D   D   D   D   D   S
	0    4    8    12    16    20    24    28    32    36    40    44    48    52    56    60 63

When a signed-packed-decimal operand resides in a general-register pair, the leftmost 64 bits of the operand occupy the even-numbered register of the pair

and the rightmost 64 bits occupy the odd-numbered register, as shown below.

GR <sub>even</sub>	D   D   D   D   D   D   D   D   D   D   D   D   D   D   D   D
	0    4    8    12    16    20    24    28    32    36    40    44    48    52    56    60 63

GR <sub>odd</sub>	D   D   D   D   D   D   D   D   D   D   D   D   D   D   D   S
	64    68    72    76    80    84    88    92    96    100    104    108    112    116    120    127

### Unsigned-Packed-Decimal Format

In the unsigned-packed-decimal format, each byte contains two 4-bit decimal digits (D) and there is no sign.

When an unsigned-packed-decimal operand resides in a general register, the operand is 64 bits (16 digits), as shown below.

GR	D   D   D   D   D   D   D   D   D   D   D   D   D   D   D   D
	0    4    8    12    16    20    24    28    32    36    40    44    48    52    56    60 63

When an unsigned-packed-decimal operand resides in a general-register pair, the leftmost 64 bits of the operand occupy the even-numbered register of the pair and the rightmost 64 bits occupy the odd-numbered register, as shown below.

GR <sub>even</sub>	D   D   D   D   D   D   D   D   D   D   D   D   D   D   D   D
	0    4    8    12    16    20    24    28    32    36    40    44    48    52    56    60 63

GR <sub>odd</sub>	D   D   D   D   D   D   D   D   D   D   D   D   D   D   D   D
	64    68    72    76    80    84    88    92    96    100    104    108    112    116    120    127

### IEEE Exceptions

The IEEE exceptions for the DFP instructions are described in the section “IEEE Exceptions” on page 9-16

### Summary of Preferred Quantum

Figure 20-4 on page 20-9 summarizes all preferred quanta.

Operations	Delivered value	Preferred Quantum
ADD	Exact	The smaller quantum of the two source operands†
	Inexact	The smallest quantum of cohort members
CONVERT FROM FIXED	Exact	One†
	Inexact	The smallest quantum of cohort members
CONVERT FROM SIGNED PACKED	--	One
CONVERT FROM UNSIGNED PACKED	--	One
DIVIDE	Exact	The quantum of the dividend divided by the quantum of the divisor†
	Inexact	The smallest quantum of cohort members
INSERT BIASED EXPONENT	--	The quantum corresponds to the requested biased exponent
LOAD AND TEST	--	The quantum of the source operand
LOAD FP INTEGER	Exact	The larger value of one and the quantum of the source operand
	Inexact	One
LOAD LENGTHENED	Exact*	The quantum of the source operand
LOAD ROUNDED	Exact	The quantum of the source operand†
	Inexact	The smallest quantum of cohort members
PERFORM FLOATING POINT OPERATION (DPQC=0)‡	Exact	The largest quantum of cohort member†
	Inexact	The smallest quantum of cohort members
PERFORM FLOATING POINT OPERATION (DPQC=1)‡	Exact	One†
	Inexact	The smallest quantum of cohort members
MULTIPLY	Exact	The product of the quanta of the two source operands†
	Inexact	The smallest quantum of cohort members
QUANTIZE	Exact	The requested quantum
	Inexact	The requested quantum
REROUND	Exact	See the instruction description
	Inexact	The quantum that corresponds to the requested significance
SHIFT SIGNIFICAND LEFT	--	The quantum of the source operand
SHIFT SIGNIFICAND RIGHT	--	The quantum of the source operand
SUBTRACT	Exact	The smaller quantum of the two source operands†
	Inexact	The smallest quantum of cohort members

**Explanation:**

- \* This is true due to a condition to the left of the column.
- For these operations, the concept of exact result or inexact result does not apply.
- † If the delivered value cannot be represented with the preferred quantum, it is represented with the quantum closest to the preferred quantum.
- ‡ Applicable only when the operation-type code is 01 hex (PFPO Convert Floating-Point Radix).
- DPQC DFP preferred quantum control.

Figure 20-4. Summary of Preferred Quantum

## Summary of Rounding And Range Actions

Figure 20-5 on page 20-10 and page 20-11 summarizes rounding and range actions.

Range of v	Case	Nontrap Result (r) when Effective Rounding Method Is							
		RNTE	RNTZ	RNTA	RA	RM	RFS	RP	RZ
v < -Nmax, g < -Nmax	Overflow	- $\infty^1$	- $\infty^1$	- $\infty^1$	- $\infty^1$	- $\infty^1$	-Nmax	-Nmax	-Nmax
v < -Nmax, g = -Nmax	Normal	-Nmax	-Nmax	-Nmax	—	—	-Nmax	-Nmax	-Nmax
-Nmax ≤ v ≤ -Nmin	Normal	g	g	g	g	g	g	g	g
-Nmin < v ≤ -Dmin	Tiny	d*	d*	d*	d*	d*	d*	d	d

**Explanation:**

- This situation cannot occur.
- \* The rounded value, in the extreme case, may be Nmin. In this case, the exceptions are underflow, inexact and incremented.
- <sup>1</sup> The nontrap result r is considered to have been incremented.
- d The value derived when the precise intermediate value (v) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note \*, this is a subnormal number.
- g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
- v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For LOAD ROUNDED, v is the source value.
- EZD Exact zero difference. The case applies only to ADD and SUBTRACT. For all other DFP operations, a zero result is detected by inspection of the source operands without use of the R(v) function.
- Dmin Smallest (in magnitude) representable subnormal number in the target format.
- Nmax Largest (in magnitude) representable finite number in the target format.
- Nmin Smallest (in magnitude) representable normal number in the target format.
- RNTA Round to nearest with ties away from 0.
- RNTE Round to nearest with ties to even.
- RNTZ Round to nearest with ties toward 0.
- RA Round away from 0.
- RFS Round to prepare for shorter precision.
- RM Round toward - $\infty$ .
- RP Round toward  $+\infty$ .
- RZ Round toward 0.

Tiny	Yes	—	1	—	—	Yes	Yes	Tw(g ÷ Ψ), PIDuy(1C)

**Explanation:**

- The results do not depend on this condition or mask bit.
- <sup>1</sup> This condition is true by virtue of the state of some condition to the left of this column.
- Ψ Scale factor. For overflow,  $\Psi=2^{+\alpha}$ . For underflow,  $\Psi=2^{-\alpha}$ . The unsigned scaling exponent ( $\alpha$ ) depends on the type of operation and operand format. For all DFP operations except LOAD ROUNDED,  $\alpha$  depends on the target format and is 576 for long, and 9216 for extended. For LOAD ROUNDED,  $\alpha$  depends on the source format and is 192 for long and 3072 for extended.
- g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
- r Nontrap result as defined in Part 1 of this figure.
- v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.
- PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-7 on page 20-13.
- SFo IEEE overflow flag, FPC 1.2.
- SFu IEEE underflow flag, FPC 1.3.
- SFx IEEE inexact flag, FPC 1.4.
- T(x) The value x is placed at the target operand location.
- Tw(x) The scaled result x is placed at the target operand location. For all DFP operations except LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

Figure 20-5. (Part 2 of 2) Rounding and Range Actions

## Result Figures

Concise descriptions of the results produced by many of the DFP instructions are made by means of figures which contain columns and rows representing all possible combinations of DFP data class for the source operands of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross-reference to another figure. In many cases, the information shown at the intersection consists of several symbols separated by commas. All such results are produced unless one of the results is a program interruption. In the case of a program interruption, the operation is suppressed or completed as shown in Figure 20-7 on page 20-13.

## Data-Exception Codes (DXC) and Abbreviations

Figure 20-6 shows IEEE exceptions and flag abbreviations that are used in the result figures, and it explains the symbols “Xi:” and “Xz:” that are used in the figures. Bits 0-4 (i,z,o,u,x) of the eight-bit data-exception code (DXC) in byte 2 of the FPC register are trap flags and correspond to the same bits in bytes 0 and 1 of the register (IEEE masks and IEEE flags). The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit. Bit 5 (y) of byte 2 is used in conjunction with

bit 4, inexact (x), to indicate that the result has been incremented in magnitude.

Figure 20-7 on page 20-13 shows the various DXCs that can be indicated, the associated instruction endings, and abbreviations that are used for the DXCs in the result figures. (The abbreviation “PID” stands for “program interruption for a data exception.”)

Exception		FPC IEEE Mask bit	IEEE Flag	
Name	Abbr.		FPC Bit	Abbr.
IEEE invalid operation	Xi <sup>1</sup>	0.0	1.0	SFi
IEEE division by zero	Xz <sup>2</sup>	0.1	1.1	SFz
IEEE overflow	Xo	0.2	1.2	SFo
IEEE underflow	Xu	0.3	1.3	SFu
IEEE inexact	Xx	0.4	1.4	SFx

**Explanation:**

<sup>1</sup> The symbol “Xi:” followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 80 hex, and a program interruption for a data exception occurs.

<sup>2</sup> The symbol “Xz:” followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 40 hex, and a program interruption for a data exception occurs.

Figure 20-6. IEEE Exception and Flag Abbreviations

<b>Abbr.</b>	<b>DXC (hex)</b>	<b>Data-Exception-Code Name</b>	<b>Instruction Ending</b>

PIDz	40	IEEE division by zero	Suppress
PIDI	80	IEEE invalid operation	Suppress

Figure 20-7. IEEE Data-Exception Codes (DXC) and Abbreviations

The figure indicates, in the column labeled “Characteristics,” the instruction format, when the condition code is set, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All DFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. For the DFP instructions to be executed successfully, the AFP-register-control bit must be one; otherwise, a DFP-instruction data exception, DXC 3, is recognized.

Mnemonics for the DFP instructions are distinguished from corresponding HFP or BFP instructions by a T in the mnemonic. Mnemonics for the DFP instructions have an R as the last letter when the instruction is in the RRE, RRF, or RRR format. Certain letters are used for DFP instructions to represent operand-format length, as follows:

- G Sixty-four-bit fixed point
- E Short
- D Long
- X Extended

**Note:** In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (long), for example, CDTR is the mnemonic and  $R_1, R_2$  the operand designation.

## Instructions

The Decimal-Floating-Point (DFP) instructions and their mnemonics and operation codes are listed in Figure 20-8 on page 20-13.

## ADD

Mnemonic	R <sub>1</sub> ,R <sub>2</sub> ,R <sub>3</sub>	[RRR]
Op Code	R <sub>3</sub>	R <sub>1</sub> R <sub>2</sub>
0	16	20 24 28 31
<b>Mnemonic</b>	<b>Op Code</b>	<b>Operands</b>
ADTR	'B3D2'	Long DFP
AXTR	'B3DA'	Extended DFP

The third operand is added to the second operand, and the sum is placed at the first-operand location.

If both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current DFP rounding mode. The sum is then placed at the result location.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operands with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward  $-\infty$ , in which method the sign is minus.

- The sign of the sum x plus x is the sign of x, even when x is zero.

If one operand is an infinity and the other is a finite number, the result is an infinity with the sign of the source infinity. If both operands are infinities of the same sign, the result is an infinity with the same sign. If the two operands are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

When the delivered value is exact, the preferred quantum is the smaller quantum of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-10 on page 20-17 for a detailed description of the results of this instruction. (Figure 20-9 is referred to by Figure 20-10.)

For AXTR, the R fields designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

### **Resulting Condition Code:**

- 0 Result is zero
- 1 Result is less than zero

- 2 Result is greater than zero
- 3 Result is a NaN

***IEEE Exceptions:***

- Invalid operation
- Overflow
- Underflow
- Inexact

***Program Exceptions:***

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (AXTR only)

Value of Result (r)	Condition code
r = 0	cc0
r < 0	cc1
r > 0	cc2

**Explanation:**

ccn Condition code is set to n.

Figure 20-9. Condition Code for Resultant Sum

**Programming Notes:**

1. Interchanging the two operands in a DFP addition does not affect the value of the sum when the result is numeric. This is not true, however, when both operands are QNaNs; or when both operands are SNaNs and the IEEE invalid-operation mask bit in the FPC register is zero, in these cases, the result is the canonical QNaN derived from the second operand.
2. For ADD or SUBTRACT, when the delivered value is inexact, the preferred quantum is the smallest quantum which is the same quantum as that closest to the smaller quantum of the two source operands.

**Explanation:**

\* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.  
ccn Condition code is set to n.

ccrs Condition code is set according to the resultant sum. See Figure 20-9 on page 20-16.

dNaN Default NaN.

Nn Normal number.

R(v) Rounding and range action is performed on the value v. See Figure 20-5 on page 20-10. The result is canonical.

Rezd Exact zero-difference result. See Figure 20-5 on page 20-10.

Dn Subnormal number.

T(x) The canonical result x is placed at the target operand location.

Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-10. Results: ADD

**COMPARE**

Mnemonic R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic Op Code Operands

CDTR 'B3E4' Long DFP  
CXTR 'B3EC' Extended DFP

The first operand is compared with the second operand, and the condition code is set to indicate the result.

If both operands are finite numbers, the comparison is algebraic and follows the procedure for DFP subtraction, except that the difference is discarded after setting the condition code, and both operands remain unchanged. If the difference is exactly zero with either sign, the operands are equal; this includes zero operands (so +0 equals -0). If a nonzero difference is positive or negative, the first operand is high or low, respectively.

+∞ compares greater than any finite number, and all finite numbers compare greater than -∞. Two infinity operands of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operands as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operands are QNaNs and neither operand is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operands are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE-invalid-operation mask bit is one, a program interrupt

for a data exception with DXC 80 hex (IEEE invalid operation) occurs. If the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 20-11 on page 20-18 for a detailed description of the results of this instruction.

For CXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (CXTR only)

## COMPARE AND SIGNAL

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
Op Code		R <sub>1</sub> R <sub>2</sub>

Mnemonic	Op Code	Operands
KDTR	'B3E0'	Long DFP
KXTR	'B3E8'	Extended DFP

The first operand is compared with the second operand, and the condition code is set to indicate the result. The operation is the same as for COMPARE

except that QNaN operands cause an IEEE-invalid-operation exception to be recognized. Thus QNaN operands are treated as if they were SNaNs.

See Figure 20-13 on page 20-19 for a detailed description of the results of this instruction.

For KXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### **Resulting Condition Code:**

0 Operands equal

- 1 First operand low
- 2 First operand high
- 3 Operands unordered

#### **IEEE Exceptions:**

- Invalid operation

#### **Program Exceptions:**

- Data with DXC 3, DFP instruction

## COMPARE BIASED EXPONENT

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
Op Code		R <sub>1</sub> R <sub>2</sub>
0	16 24 28	31

Mnemonic	Op Code	Operands
CEDTR	'B3F4'	Long DFP
CEXTR	'B3FC'	Extended DFP

The biased exponent of the first operand is compared with the biased exponent of the second operand, and the condition code is set to indicate the result.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

See Figure 20-14 on page 20-20 for a detailed description of the results of this instruction.

For CEXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### **Resulting Condition Code:**

- 0 Biased exponents equal
- 1 First-operand biased exponent low
- 2 First-operand biased exponent high
- 3 Unordered

#### **IEEE Exceptions:** None.

#### **Program Exceptions:**

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CEXTR only)

First operand (a) is	Result for COMPARE BIASED EXPONENT when second operand (b) is			
	F	$\infty$	QNaN	SNaN
F	$C(e_a:e_b)$	cc3	cc3	cc3
$\infty$	cc3	cc0	cc3	cc3
QNaN	cc3	cc3	cc0	cc0
SNaN	cc3	cc3	cc0	cc0

**Explanation:**

$C(e_a:e_b)$  Biased-exponent compare results. See Figure 20-15 on page 20-20.

ccn Condition code is set to n.

F All finite numbers, including zeros.

Figure 20-14. Results: COMPARE BIASED EXPONENT

Relation of value $e_a$ to value $e_b$	Condition Code for $C(e_a:e_b)$
$e_a = e_b$	cc0
$e_a < e_b$	cc1
$e_a > e_b$	cc2

**Explanation:**

ccn Condition code is set to n.

$e_a$  Biased exponent of the first operand

$e_b$  Biased exponent of the second operand

## CONVERT FROM FIXED

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
Op Code		R <sub>1</sub> R <sub>2</sub>

Mnemonic	Op Code	Operands
CDGTR	'B3F1'	64-bit binary-integer source, long DFP result
CXGTR	'B3F9'	64-bit binary-integer source, extended DFP result

The fixed-point second operand is converted to the DFP format, and the result is placed at the first-operand location.

The second operand is a 64-bit signed binary integer that is located in the general register designated by R<sub>2</sub>.

The result is rounded according to the current DFP rounding mode before it is placed at the first-operand location.

When the delivered value is exact, the preferred quantum is one; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-21 on page 20-28 for a detailed description of the results of this instruction.

For CXGTR, the R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### IEEE Exceptions:

- Inexact (CDGTR only)

### Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (CXGTR only)

## CONVERT FROM SIGNED PACKED

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
Op Code		R <sub>1</sub> R <sub>2</sub>

Mnemonic	Op Code	Operands
CDSTR	'B3F3'	64-bit signed-packed-decimal source in GR, long DFP result
CXSTR	'B3FB'	128-bit signed-packed-decimal source in GRs, extended DFP result

The second operand in the signed-packed-decimal format is converted to the DFP format, and the result is placed at the first-operand location.

The second operand is located in the general register or general-register pair designated by R<sub>2</sub>.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

When an invalid digit or sign code is detected in the second operand, a decimal-operand data exception is recognized.

For CXSTR, the R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R<sub>2</sub> field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 0, decimal operand
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CXSTR only)

## CONVERT FROM UNSIGNED PACKED

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]	
Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic	Op Code	Operands
CDUTR	'B3F2'	64-bit unsigned-packed-decimal source in GR, long DFP result
CXUTR	'B3FA'	128-bit unsigned-packed-decimal source in GRs, extended DFP result

The second operand in the unsigned-packed-decimal format is converted to the DFP format with a positive sign, and the result is placed at the first-operand location.

The second operand is located in the general register or general-register pair designated by R<sub>2</sub>.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

When an invalid digit code is detected in the second operand, a decimal-operand data exception is recognized.

For CXUTR, the R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R<sub>2</sub> field designates

an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 0, decimal operand
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CXUTR only)

## CONVERT TO FIXED

Mnemonic	R <sub>1</sub> ,M <sub>3</sub> ,R <sub>2</sub>	[RRF]		
Op Code	M <sub>3</sub>		R <sub>1</sub>	R <sub>2</sub>
0		16	20	24 28 31

Mnemonic	Op Code	Operands
CGDTR	'B3E1'	Long DFP source, 64-bit binary-integer result
CGXTR	'B3E9'	Extended DFP source, 64-bit binary-integer result

The DFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a 64-bit signed binary integer that is placed in the general register designated by R<sub>1</sub>.

If the second operand is numeric and finite, it is rounded to an integer value by rounding as specified by the modifier in the M<sub>3</sub> field:

#### M<sub>3</sub> Effective Rounding Method

- |     |  |
|-----|--|
| 0   | According to the current DFP rounding mode |
| 1-7 | Reserved                                   |
| 8   | Round to nearest with ties to even         |
| 9   | Round toward 0                             |
| 10  | Round toward +∞                            |
| 11  | Round toward -∞                            |
| 12  | Round to nearest with ties away from 0     |
| 13  | Round to nearest with ties toward 0        |
| 14  | Round away from 0                          |
| 15  | Round to prepare for shorter precision     |

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the

FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. When the modifier field is a reserved value, it is unpredictable which rounding method is performed.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

See Figure 20-16 for a detailed description of the results of this instruction.

For CGXTR, the R<sub>2</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

#### **Resulting Condition Code:**

- 0 Source was zero
- 1 Source was less than zero
- 2 Source was greater than zero

Operand (b)	Is n Inexact (n ≠ b)	Invalid-Op. Mask (FPC 0.0)	Inexact Mask (FPC 0.4)	Is n Incremented ( n  >  b )	Results

Figure 20-16. Results: CONVERT TO FIXED (Part 1 of 2)

### 3 Special case

#### **IEEE Exceptions:**

- Invalid operation
- Inexact

#### **Program Exceptions:**

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (CGXTR only)

#### **Programming Notes:**

1. Rounding for modifiers 8-15 is the same as for DFP rounding modes 0-7 (binary 000-111), respectively.
2. The effective rounding methods listed in M<sub>3</sub> as reserved are set aside for future extensions

Operand (b)	Is n Inexact (n ≠ b)	Invalid-Op. Mask (FPC 0.0)	Inexact Mask (FPC 0.4)	Is n Incremented ( n  >  b )	Results
NaN	—	1	—	—	PIDi(80)

**Explanation:**

- The results do not depend on this condition or mask bit.
- <sup>1</sup> This condition is true by virtue of the state of some condition to the left of this column.
- <sup>2</sup> The n=MN and n=MP conditions only applies to CGXTR.
- ccn Condition code is set to n.
- † Result differs from BFP CONVERT TO FIXED. The BFP instruction recognizes inexact for this case and takes different actions depending on the inexact mask. The DFP implementation is intended to be more in keeping with the spirit of the IEEE standard.
- f The value n converted to a fixed-point result.
- n The value derived when the source value (a) is rounded to a floating-point integer using the effective rounding method.
- MN Maximum negative number representable in the target fixed-point format.
- MP Maximum positive number representable in the target fixed-point format.
- PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. Figure 20-7 on page 20-13
- SFi IEEE invalid-operation flag, FPC 1.0.
- SFx IEEE inexact flag, FPC 1.4.
- T(x) The value x is placed at the target operand location

Figure 20-16. Results: CONVERT TO FIXED (Part 2 of 2)

## CONVERT TO SIGNED PACKED

Mnemonic	R <sub>1</sub> ,R <sub>2</sub> ,M <sub>4</sub>	[RRF]
	Op Code      //    M <sub>4</sub>   R <sub>1</sub>   R <sub>2</sub>	0                 16 20 24 28 31

Mnemonic	Op Code	Operands
CSDTR	'B3E3'	Long DFP source, 64-bit signedpacked-decimal result in GR
CSXTR	'B3EB'	Extended DFP source, 128-bit signed-packed-decimal result in GRs

Rightmost significand digits of the DFP second operand are converted to the signed-packed-decimal format, and the result is placed at the first-operand location.

For CSDTR, the rightmost 15 digits in the trailing significand and the sign bit of the second operand are converted to a 64-bit result (15 4-bit decimal digits and a 4-bit sign); for CSXTR, the rightmost 31 digits in the trailing significand and the sign bit of the second operand are converted to a 128-bit result (31 4-bit decimal digits and a 4-bit sign). The sign of the result is the sign of the second operand.

Bit 3 of the M<sub>4</sub> field is the plus sign-code selection bit. When the bit is zero, the plus sign is encoded as 1100; when the bit is one, the plus sign is encoded as 1111. Bits 0-2 are ignored.

The result is placed in the general register or general-register pair designated by R<sub>1</sub>.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For CSXTR, the R<sub>2</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R<sub>1</sub> field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CSXTR only)

**Programming Notes:**

1. Bits 0-2 of the M<sub>4</sub> field are reserved for future extensions and should be set to zeros.
2. The sign code 1100 is the System z preferred plus sign, and 1111 is the System i preferred plus sign.

## CONVERT TO UNSIGNED PACKED

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]	
Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic	Op Code	Operands
CUDTR	'B3E2'	Long DFP source, 64-bit unsigned-packed-decimal result in GR
CUXTR	'B3EA'	Extended DFP source, 128-bit unsigned-packed-decimal result in GRs

Rightmost significand digits of the DFP second operand are converted to the unsigned-packed-decimal format, and the result is placed at the first-operand location.

For CUDTR, 16 significand digits of the second operand are converted to a 64-bit result (16 4-bit decimal digits). If the second operand is an infinity or NaN, the 15 digits in the trailing significand are padded with a zero digit on the left to form a 16 significand digits.

For CUXTR, the rightmost 32 digits in the trailing significand of the second operand are converted to a 128-bit result (32 4-bit decimal digits).

The result is placed in the general register or general-register pair designated by R<sub>1</sub>.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For CUXTR, the R<sub>2</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R<sub>1</sub> field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CUXTR only)

## DIVIDE

Mnemonic	R <sub>1</sub> ,R <sub>2</sub> ,R <sub>3</sub>	[RRR]		
Op Code	R <sub>3</sub>		R <sub>1</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic	Op Code	Operands
DDTR	'B3D1'	Long DFP
DXTR	'B3D9'	Extended DFP

The second operand (the dividend) is divided by the third operand (the divisor), and the quotient is placed at the first-operand location. No remainder is preserved.

If divisor is nonzero and both the dividend and divisor are finite numbers, the second operand is divided by the third operand to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format according to the current DFP rounding mode.

When the dividend is a finite number and the divisor is infinity, then a value of zero with zero significand and zero biased exponent is produced.

The sign of the quotient, if the quotient is numeric, is the exclusive OR of the operand signs. This includes the sign of a zero or infinite quotient.

When the delivered value is exact, the preferred quantum is the quantum of the dividend divided by the quantum of the divisor; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

If the divisor is zero but the dividend is nonzero and finite, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinite, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 20-17 on page 20-25 for a detailed description of the results of this instruction.

For DXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Invalid operation
- Division by zero
- Overflow
- Underflow
- Inexact

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (DXTR only)

Dividend (b) is	Results for DIVIDE (b ÷ c) when divisor (c) is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
-∞	Xi: T(dNaN)	T(+∞)	T(+∞)	T(-∞)	T(-∞)	Xi: T(dNaN)	T(c)	Xi: T(c*)
-Fn	T(+zt)	R(b÷c)	Xz: T(+∞)	Xz: T(-∞)	R(b÷c)	T(-zt)	T(c)	Xi: T(c*)
-0	T(+zt)	T(+0)	Xi: T(dNaN)	Xi: T(dNaN)	T(-0)	T(-zt)	T(c)	Xi: T(c*)
+0	T(-zt)	T(-0)	Xi: T(dNaN)	Xi: T(dNaN)	T(+0)	T(+zt)	T(c)	Xi: T(c*)
+Fn	T(-zt)	R(b÷c)	Xz: T(-∞)	Xz: T(+∞)	R(b÷c)	T(+zt)	T(c)	Xi: T(c*)
+∞	Xi: T(dNaN)	T(-∞)	T(-∞)	T(+∞)	T(+∞)	Xi: T(dNaN)	T(c)	Xi: T(c*)
QNaN	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	Xi: T(c*)
SNaN	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)

**Explanation:**

\* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.

dNaN Default NaN.

Fn Nonzero finite number (includes both subnormal and normal numbers).

R(x) Rounding and range action is performed on the value x. See Figure 20-5 on page 20-10. The result is canonical.

T(x) The canonical result x is placed at the target operand location.

Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Xz: IEEE division-by-zero exception. The results shown are produced only when FPC 0.1 is zero.

zt A value of zero with zero significand and zero biased exponent.

Figure 20-17. Results: DIVIDE

**Programming Note:** For DIVIDE, when the delivered value is inexact, the preferred quantum is the smallest quantum which is not always the same quantum as that closest to the quantum of the dividend divided by the quantum of the divisor.

For example, with the short data format, when  $5000001 \times 10^{-7}$  is divided by  $400 \times 10^0$ , the smallest quantum for the delivered value is  $1 \times 10^{-9}$ . However, the quantum that is closest to the quantum of the dividend divided by the quantum of the divisor is  $1 \times 10^{-7}$ .

**EXTRACT BIASED EXPONENT**

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]
	Op Code   / / / / /   R <sub>1</sub>   R <sub>2</sub>	0            16            24            28            31

Mnemonic	Op Code	Operands
EEDTR	'B3E5'	Long DFP source, 64-bit binary-integer result
EEXTR	'B3ED'	Extended DFP source, 64-bit binary-integer result

The biased exponent of the DFP second operand is placed at the first-operand location.

When the second operand is a finite number, the biased exponent of the second operand is placed at the first-operand location. When the second operand is an infinity, QNaN, or SNaN, a special value is placed at the first-operand location.

The result is a 64-bit signed binary integer that is placed in the general register designated by R<sub>1</sub>.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

See Figure 20-18 for a detailed description of the results of this instruction.

Second-operand data	First-operand value
Finite number	e
Infinity	-1
QNaN	-2
SNaN	-3

**Explanation:**

e	Biased exponent
---	-----------------

Figure 20-18. Results: EXTRACT BIASED EXPONENT

For EEXTR, the R<sub>2</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (EEXTR only)

## EXTRACT SIGNIFICANCE

Mnemonic R<sub>1</sub>,R<sub>2</sub> [RRE]

Op Code		R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic	Op Code	Operands
ESDTR	'B3E7'	Long DFP source, 64-bit binary-integer result
ESXTR	'B3EF'	Extended DFP source, 64-bit binary-integer result

The number of DFP significant digits of the DFP second operand is placed at the first-operand location.

When the second operand is a finite number, the result is set to the number of DFP significant digits of the second operand. When the second operand is an infinity, QNaN, or SNaN, the result is set to -1, -2, or -3, respectively.

The result is a 64-bit signed binary integer that is placed in the general register designated by R<sub>1</sub>.

See Figure 20-19 for a detailed description of the results of this instruction.

Second-operand data	First-operand value
Nonzero finite number	NSD
Zero	0
Infinity	-1
QNaN	-2
SNaN	-3

**Explanation:**

NSD	The number of DFP significant digits of the second operand.
-----	---

Figure 20-19. Results: EXTRACT SIGNIFICANCE

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For ESXTR, the R<sub>2</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (ESXTR only)

## INSERT BIASED EXPONENT

Mnemonic R<sub>1</sub>,R<sub>3</sub>,R<sub>2</sub> [RRF]

Op Code	R <sub>3</sub>		R <sub>1</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic	Op Code	Operands
IEDTR	'B3F6'	Long DFP
IEXTR	'B3FE'	Extended DFP

A DFP operand is produced by combining the requested biased exponent with the sign bit and the significand of the DFP third operand, and the result is placed in the first-operand location.

The value of the requested biased exponent is a 64-bit signed binary integer and is located in the general register designated by R<sub>2</sub>.

When the value of the requested biased exponent is in the range between zero and the maximum biased exponent, inclusively, for the target format, the result is a finite number. The biased exponent of the result is set to the value of the requested biased exponent; the significand of the result is set to the significand of the third operand. If the third operand is an infinity or NaN, the significand of the third operand contains the digits in the trailing significand of the third operand padded with a zero digit on the left.

When the value of the requested biased exponent is -1, the result is an infinity. The reserved field of the result is set to zero; the trailing significand of the result is set to the trailing significand of the third operand.

When the value of the requested biased exponent is equal to -2, less than -3, or greater than the maximum biased exponent for the target format, the result is a QNaN; when the value of the requested biased exponent is -3, the result is an SNaN. When a NaN is produced as the result, the reserved field of the result is set to zero, and the trailing significand of the result is set to the trailing significand of the third operand.

The sign of the result is the same as the sign of the third operand.

The preferred quantum is the quantum that corresponds to the requested biased exponent. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the third operand are zeros, then the result is a canonical infinity; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

See Figure 20-20 for a detailed description of the results of this instruction.

This operation is performed for any requested biased exponent and any third operand without causing an IEEE exception.

Value (b) in second operand	Results <sup>1</sup> for INSERT BIASED EXPONENT when third operand (c) is			
	F	$\infty$	QNaN	SNaN
b > MBE	T(QNaN)	T(QNaN)	T(QNaN)	T(QNaN)
MBE $\geq b \geq 0$	T(F)	T(F <sup>2</sup> )	T(F <sup>2</sup> )	T(F <sup>2</sup> )
b = -1	N( $\infty$ )	N( $\infty$ )	N( $\infty$ )	N( $\infty$ )
b = -2	T(QNaN)	T(QNaN)	T(QNaN)	T(QNaN)
b = -3	T(SNaN)	T(SNaN)	T(SNaN)	T(SNaN)
B $\leq -4$	T(QNaN)	T(QNaN)	T(QNaN)	T(QNaN)

**Explanation:**

- <sup>1</sup> The sign of the result is the same as the sign of the third operand.
- <sup>2</sup> The leftmost digit of the significand is zero.
- F All finite numbers, including zeros.
- MBE Maximum biased exponent for the target format.
- N( $\infty$ ) The result is a canonical infinity if all digits in the trailing significand of the third operand are zeros; otherwise, the resultant infinity has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.
- T(x) The canonical result x is placed at the target operand location.

Figure 20-20. Results: INSERT BIASED EXPONENT

For IEXTR, the R<sub>1</sub> and R<sub>3</sub> fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (IEXTR only)

**Programming Note:** Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

## LOAD AND TEST

Mnemonic	R <sub>1</sub> ,R <sub>2</sub>	[RRE]	
Op Code	////////	R <sub>1</sub>	R <sub>2</sub>
0	16	24	28 31

Mnemonic	Op Code	Operands
LTDTR	'B3D6'	Long DFP
LTXTR	'B3DE'	Extended DFP

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

The second operand is canonicalized before it is placed at the first-operand location. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN.

The preferred quantum is the quantum of the second operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-21 for a detailed description of the results of this instruction.

For LTXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

### Resulting Condition Code:

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 Result is a NaN

### IEEE Exceptions:

- Invalid operation

### Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LTXTR only)

Instruction	Results for some instructions with a single operand (b) when second operand (b) is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
CONVERT FROM FIXED	—	Rf(b)	—	T(+0)	Rf(b)	—	—	—
LOAD AND TEST	T(-∞)	T(b)	T(-0)	T(+0)	T(b)	T(+∞)	T(b)	Xi: T(b*)
LOAD LENGTHENED (XiC = 0)	T(-∞)	T(b) <sup>1</sup>	T(-0)	T(+0)	T(b) <sup>1</sup>	T(+∞)	T(b) <sup>1</sup>	Xi: T(b*) <sup>1</sup>
LOAD LENGTHENED (XiC = 1)	N(-∞) <sup>1</sup>	T(b) <sup>1</sup>	T(-0)	T(+0)	T(b) <sup>1</sup>	N(+∞) <sup>1</sup>	T(b) <sup>1</sup>	T(b) <sup>1</sup>
LOAD ROUNDED (XiC = 0)	T(-∞)	R(b)	T(-0)	T(+0)	R(b)	T(+∞)	T(b) <sup>2</sup>	Xi: T(b*) <sup>2</sup>
LOAD ROUNDED (XiC = 1)	N(-∞) <sup>2</sup>	R(b)	T(-0)	T(+0)	R(b)	N(+∞) <sup>2</sup>	T(b) <sup>2</sup>	T(b) <sup>2</sup>

**Explanation:**

— The results do not depend on this condition.

\* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.

<sup>1</sup> The operand is extended to the longer format by appending zeros on the left before it is placed at the target operand location.

<sup>2</sup> The operand is shortened to the target format by truncating the leftmost digits.

Fn Nonzero finite number (includes both subnormal and normal).

N(±∞) The resultant infinity has the reserved field set to zero and has canonical declets in the encoded trailing-significand field. The result is not considered canonical unless all digits in the trailing significand are zeros.

R(v) Rounding and range action is performed on the value v. See Figure 20-5 on page 20-10. The result is canonical.

Rf(b) The value b is converted to the exact floating-point number v, and then action R(v) is performed. The result is canonical.

T(x) The canonical result x is placed at the target operand location.

Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

XiC IEEE-invalid-operation-exception control, bit 0 of the M<sub>4</sub> field.

Figure 20-21. Results: Some Single-Operand Instructions

## LOAD FP INTEGER

Mnemonic	R <sub>1</sub> ,M <sub>3</sub> ,R <sub>2</sub> ,M <sub>4</sub>	[RRF]			
Op Code	M <sub>3</sub>	M <sub>4</sub>	R <sub>1</sub>	R <sub>2</sub>	
0	16	20	24	28	31

Mnemonic	Op Code	Operands
FIDTR	'B3D7'	Long DFP
FIXTR	'B3DF'	Extended DFP

The second operand is rounded to an integer value in the same floating-point format, and the result is placed at the first-operand location.

The second operand, if a finite number, is rounded to an integer value as specified by the modifier in the M<sub>3</sub> field:

### M<sub>3</sub> Effective Rounding Method

- |     |  |
|-----|--|
| 0   | According to the current DFP rounding mode |
| 1-7 | Reserved                                   |
| 8   | Round to nearest with ties to even         |
| 9   | Round toward 0                             |
| 10  | Round toward +∞                            |
| 11  | Round toward -∞                            |
| 12  | Round to nearest with ties away from 0     |
| 13  | Round to nearest with ties toward 0        |
| 14  | Round away from 0                          |
| 15  | Round to prepare for shorter precision     |

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. When the modifier field is a reserved value, it is unpredictable which rounding method is performed.

In the absence of an interruption, if the second operand is an infinity, the result is the canonical infinity; if the second operand is a QNaN, the result is the canonicalized source QNaN that has the same sign and payload as the source; if the second operand is an SNaN, the result is the corresponding QNaN.

The sign of the result is the sign of the second operand, even when the result is zero.

Bit 1 of the M<sub>4</sub> field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored.

When the result differs in value from the second operand, if XxC is zero, an IEEE-inexact exception is

recognized. If XxC one, then no IEEE-inexact exception is recognized.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

When the delivered value is exact, the preferred quantum is the larger value of one and the quantum of the second operand; when the delivered value is inexact, the preferred quantum is one. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-22 on page 20-30 for a detailed description of the results of FIDTR and FIXTR.

For FIXTR, the R fields must designate valid floating-point-register fields; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### IEEE Exceptions:

- Invalid operation
- Inexact (XxC = 0 only)

### Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (FIXTR only)

### Programming Notes:

1. The effective rounding methods listed in M<sub>3</sub> as reserved are set aside for future extensions.
2. Rounding for modifiers 8-15 is the same as for DFP rounding modes 0-7 (binary 000-111), respectively.
3. Bits 0, 2, and 3 of the M<sub>4</sub> field are reserved for future extensions and should be set to zeros.
4. If the DFP source operand is numeric with a quantum of at least one so that it is already an integer, the result value and quantum remain the same. Other numeric DFP source operands that are integers with a quantum less than one are

Second Operand (b)	Is n Inexact (n ≠ b)	IEEE Inexact Exception Control (XxC)	Inexact Mask (FPC 0.4)	Is n Incremented ( n  >  b )	Inv.-Op. Mask (FPC 0.0)	Results
-∞	No <sup>1</sup>	—	—	—	—	T(-∞)
-Fn	No	—	—	—	—	T(n)
-Fn	Yes	0	0	—	—	T(n), SFx←1
-Fn	Yes	0	1	No	—	T(n), PIDx(08)
-Fn	Yes	0	1	Yes	—	T(n), PIDy(0C)
-Fn	Yes	1	—	—	—	T(n)
-0	No <sup>1</sup>	—	—	—	—	T(-0)
+0	No <sup>1</sup>	—	—	—	—	T(+0)
+Fn	No	—	—	—	—	T(n)
+Fn	Yes	0	0	—	—	T(n), SFx←1

**Explanation:**

- The results do not depend on this condition or mask bit.
- \* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- <sup>1</sup> This condition is true by virtue of the state of some condition to the left of this column.
- n The value derived when the source value, b, is rounded to an integer using the effective rounding method.
- Fn Finite nonzero number (includes both subnormal and normal).
- PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-7 on page 20-13
- SFi IEEE invalid-operation flag, FPC 1.0.
- SFx IEEE inexact flag, FPC 1.4.
- T(x) The canonical result x is placed at the target operand location. The result, when it is a finite number, is always represented with the preferred quantum.

Figure 20-22. Results: LOAD FP INTEGER

converted to the same value with a quantum of one.

5. The IEEE-inexact control (XxC) specifies if an IEEE inexact exception is recognized for an inexact result. When the exception is recognized, it further depends on the IEEE-inexact mask bit in the floating-point-control register to determine if a trap occurs.

## LOAD LENGTHENED

Mnemonic R<sub>1</sub>,R<sub>2</sub>,M<sub>4</sub> [RRF]

Op Code	////	M <sub>4</sub>	R <sub>1</sub>	R <sub>2</sub>
0		16	24	28 31

Mnemonic Op Code Operands

LDETR	'B3D4'	Short DFP source, long DFP result
LXDTR	'B3DC'	Long DFP source, extended DFP result

The second operand is converted to a longer format, and the result is placed at the first-operand location.

Bit 0 of the M<sub>4</sub> field controls the handling of SNaN and infinity, and is called the IEEE-invalid-operation-exception control (XiC). Bits 1-3 are ignored.

When the second operand is a finite number, the value of the second operand is placed in the target format.

When the second operand is an infinity, if  $\text{XiC}$  is zero, the result is the canonical infinity for the target format; if  $\text{XiC}$  is one, the result is the source infinity with the reserved field of the target format being set to zero, the trailing significand being extended by appending zeros on the left, and all declets in the encoded trailing-significand field being canonicalized.

When the second operand is a QNaN, the result is the canonicalized source QNaN with the payload extended by appending zeros on the left.

When the second operand is an SNaN, if  $\text{XiC}$  is zero, an invalid-operand exception is recognized and the nontrap result is the corresponding QNaN with the payload extended by appending zeros on the left; if  $\text{XiC}$  is one, no invalid-operand exception is recognized, and the result is the canonicalized source SNaN with the payload extended by appending zeros on the left.

The sign of the result is the same as the sign of the second operand.

The delivered value is always exact and the preferred quantum is the quantum of the second operand.

When  $\text{XiC}$  is zero, the result placed at the first-operand location is canonical. When  $\text{XiC}$  is one, the result is canonical, except for infinity. See the detailed description above for producing an infinity when  $\text{XiC}$  is one.

See Figure 20-21 on page 20-28 for a detailed description of the results of this instruction.

For LXDTR, the  $R_1$  field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### IEEE Exceptions:

- Invalid operation ( $\text{XiC} = 0$  only)

#### Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LXDTR only)

#### Programming Notes:

1. Bits 1-3 of the  $M_4$  field are reserved for future extensions and should be set to zeros.
2. The equivalent operations of LOAD LENGTH-ENED (short to long) in the Power architecture do not recognize the invalid-operation exception for both BFP and DFP. The equivalent operations of LOAD LENGTHENED in z/Architecture do recognize the exception for BFP. The IEEE-invalid-operation-exception control ( $\text{XiC}$ ) is provided for compatibility.
3. Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.
4. The IEEE-invalid-operation-exception control ( $\text{XiC}$ ) specifies if an IEEE invalid-operation exception is recognized for an SNaN source operand. When the exception is recognized, it further depends on the IEEE-invalid-operation mask bit in the floating-point-control register to determine if a trap occurs.

## LOAD ROUNDED

Mnemonic	$R_1, M_3, R_2, M_4$	[RRF]
	Op Code        $M_3$   $M_4$   $R_1$   $R_2$	0              16   20   24   28   31

Mnemonic	Op Code	Operands
LEDTR	'B3D5'	Long DFP source, short DFP target, short or long DFP result
LDXTR	'B3DD'	Extended DFP source, long DFP target, long or extended DFP result

The second operand, in the format of the source, is rounded to the precision of the target, and the result is placed at the first-operand location.

The second operand, if it is a finite number, is rounded as specified by the modifier in the M<sub>3</sub> field:

#### M<sub>3</sub> Effective Rounding Method

0	According to the current DFP rounding mode
1-7	Reserved
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. When the modifier field is a reserved value, it is unpredictable which rounding method is performed.

Bit 0 of the M<sub>4</sub> field controls the handling of SNaN and infinity, and is called the IEEE-invalid-operation-exception control (XiC). Bits 1-3 are ignored.

In the absence of a trap overflow or trap underflow, the result is in the format and length of the target. However, when a trap overflow or trap underflow occurs, the operation is completed by producing a scaled result in the same format and length as the source but rounded to the precision of the target. In this case, the result is selected from a subset of the cohort for the delivered value in the source format. This subset of the cohort consists of cohort members that have the number of DFP significand digits equal to or less than the precision of the target format. For LEDTR, the result has at most seven DFP significant digits; for LDXTR, the result has at most 16 DFP significant digits.

When the second operand is an infinity, if XiC is zero, the result is the canonical infinity for the target format; if XiC is one, the result is the source infinity with the reserved field of the target format being set to zero, the trailing significand being shortened by removing leftmost digits, and declets corresponding to the shortened trailing significand being canonicalized.

When the second operand is a QNaN, the result is the canonicalized source QNaN with the payload shortened by removing leftmost digits.

When the second operand is an SNaN, if XiC is zero, an invalid-operand exception is recognized and the nontrap result is the corresponding QNaN with the payload shortened by removing leftmost digits; if XiC is one, no invalid-operand exception is recognized, and the result is the canonicalized source SNaN with the payload shortened by removing leftmost digits.

The sign of the result is the same as the sign of the second operand.

When the delivered value is exact, the preferred quantum is the quantum of the second operand; when the delivered value is inexact, the preferred quantum is the smallest quantum.

When XiC is zero, the result placed at the first-operand location is canonical. When XiC is one, the result is canonical, except for infinity. See the detailed description above for producing an infinity when XiC is one.

See Figure 20-21 on page 20-28 for a detailed description of the results of this instruction.

For LDXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

#### IEEE Exceptions:

- Invalid operation (XiC = 0 only)
- Overflow
- Underflow
- Inexact

#### Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LDXTR only)

#### Programming Notes:

1. LOAD ROUNDED and the round-to-prepare-for-shorter-precision rounding method can be used to simulate a DFP operation with the precision of

a shorter format and with the effect of single rounding. The round-to-prepare-for-shorter-precision rounding method is used by the operation, and the desirable rounding method is used by the subsequent LOAD ROUNDED instruction.

2. The effective rounding methods listed in M<sub>3</sub> as reserved are set aside for future extensions.
3. Rounding for modifiers 8-15 is the same as for DFP rounding modes 0-7 (binary 000-111), respectively.
4. Bits 1-3 of the M<sub>4</sub> field are reserved for future extensions and should be set to zeros.
5. The equivalent operation of LOAD ROUNDED (long to short) in the Power architecture does not recognize the invalid-operation exception. IEEE-invalid-operation-exception control (XiC) is provided for compatibility.
6. Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.
7. In case of a trap overflow or a trap underflow, the number of DFP significand digits of the delivered result is limited to the precision of the target format. For example, when the source operand is 75958100 X 10<sup>369</sup> and is represented with the quantum of 10<sup>369</sup>, execution of LEDTR using the round-away-from-0 rounding method produces a value of 7595810 X 10<sup>178</sup> with the delivered quantum of 10<sup>178</sup> as the trap overflow result.
8. The IEEE-invalid-operation-exception control (XiC) specifies if an IEEE invalid-operation exception is recognized for an SNAN source operand. When the exception is recognized, it further depends on the IEEE-invalid-operation mask bit in the floating-point-control register to determine if a trap occurs.

## MULTIPLY

Mnemonic	R <sub>1</sub> ,R <sub>2</sub> ,R <sub>3</sub>	[RRR]
Op Code	R <sub>3</sub>	R <sub>1</sub> R <sub>2</sub>
0	16	20 24 28 31

Mnemonic	Op Code	Operands
MDTR	'B3D0'	Long DFP
MXTR	'B3D8'	Extended DFP

The product of the second operand (the multiplicand) and the third operand (the multiplier) is placed at the first-operand location.

If both source operands are finite numbers, they are multiplied to form an intermediate product. The intermediate product is rounded to the target format according to the current DFP rounding mode.

The sign of the product, if the product is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite product.

When the delivered value is exact, the preferred quantum is the product of the quanta of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-23 on page 20-34 for a detailed description of the results of this instruction.

If one source operand is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized

For MXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

### IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

### Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (MXTR only)

### Programming Notes:

1. Interchanging the two operands in a DFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operands are QNaNs. in which

Multiplicand (b) is	Results for MULTIPLY (b • c) when multiplier (c) is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
-∞	T(+∞)	T(+∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(-∞)	T(-∞)	T(c)	Xi: T(c*)

+∞	T(-∞)	T(-∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(+∞)	T(+∞)	T(c)	Xi: T(c*)
QNaN	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	Xi: T(c*)
SNaN	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)

**Explanation:**

- \* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- dNaN Default NaN.
- Fn Nonzero finite number (includes both subnormal and normal).
- R(v) Rounding and range action is performed on the value v. See Figure 20-5 on page 20-10. The result is canonical.
- T(x) The canonical result x is placed at the target operand location.
- Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-23. Results: MULTIPLY

case the result is the canonical QNaN derived from the second operand; or when both operands are SNaNs and the IEEE invalid-operation mask bit in the FPC register is zero, in which case the result is the canonical QNaN derived from the second operand.

- For MULTIPLY, when the delivered value is inexact, the preferred quantum is the smallest quantum which is the same quantum as that closest to the product of the quanta of the two source operands.

to or larger than the requested quantum, the value of the third operand with the requested quantum is placed at the first-operand location. If the quantum of the third operand is smaller than the requested quantum, the third operand is rounded to the requested quantum by rounding as specified by the modifier in the M<sub>4</sub> field, and the result with the requested quantum is placed at the first-operand location.

#### M<sub>4</sub> Effective Rounding Method

## QUANTIZE

Mnemonic R<sub>1</sub>,R<sub>3</sub>,R<sub>2</sub>,M<sub>4</sub> [RRF]

Op Code	R <sub>3</sub>	M <sub>4</sub>	R <sub>1</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic Op Code Operands  
QADTR 'B3F5' Long DFP  
QAXTR 'B3FD' Extended DFP

The third operand is rounded to a requested quantum, and the result is placed at the first-operand location.

The requested quantum is the quantum of the second operand.

When both the second and third operands are finite numbers, if the quantum of the third operand is equal

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. When the modifier field is a reserved value, it is unpredictable which rounding method is performed.

The sign of the result, if numeric, is the same as the sign of the third operand.

This operation performs a functionally-constrained rounding, and does not recognize an underflow exception. No overflow condition can occur.

The preferred quantum is the requested quantum. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-24 on page 20-35 for a detailed description of the results of this instruction.

An invalid-operation exception is recognized when the resultant value cannot be represented in the target format with the requested quantum. When the invalid-operation exception is recognized, and if the exception is disabled, the result is the default QNaN.

An IEEE inexact exception is recognized when the result differs in value from the third operand,

For QAXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Invalid operation
- Inexact

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (QAXTR only)

When second operand (b) is	Result for QUANTIZE when third operand (c) is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
-∞	T(-∞)	Xi: T(dNaN)	Xi: T(dNaN)	Xi: T(dNaN)	Xi: T(dNaN)	T(+∞)	T(c)	Xi: T(c*)
-Fn	Xi: T(dNaN)	Q(b:c)	E(-0)	E(+0)	Q(b:c)	Xi: T(dNaN)	T(c)	Xi: T(c*)

QNaN	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	Xi: T(c*)
SNaN	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)

**Explanation:**

- \* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
- dNaN Default NaN.
- E(0) The value zero with the quantum of operand b is placed at the target operand location.
- Fn Finite nonzero number (includes both subnormal and normal).
- Q(b:c) See Figure 20-25.
- T(x) The canonical result x is placed at the target operand location.
- Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-24. Results: QUANTIZE

Relation <sup>1</sup>	Is $ Vcl  > (10^p - 1) \times 10^{Qb}$ ?	Result for Q(b:c)
$10^{Qb} < 10^{Qc}$	Yes	$Xi: T(dNaN)$
	No	$L(c)$
$10^{Qb} = 10^{Qc}$		$T(c)$
$10^{Qb} > 10^{Qc}$		$Rq(c)$

**Explanation:**

<sup>1</sup> The quantum of the second operand and the third operand is  $10^{Qb}$  and  $10^{Qc}$ , respectively.

dNaN Default NaN.

p Format precision.

Qb The right-units-view exponent of the second operand (b).

Qc The right-units-view exponent of the third operand (c).

|Vcl| The absolute value of the third operand (c).

L(c) The third operand (c) is represented with the requested quantum. The result is represented with the preferred quantum and is canonical.

Rq(c) The third operand (c) is rounded to the requested quantum. The result is represented with the preferred quantum and is canonical.

T(x) The canonical result x is placed at the target operand location. The result, when it is a finite number, is represented with the preferred quantum and is canonical.

Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-25. Results: Q(b:c)

### Programming Notes:

- When the third operand is larger than  $(10^p - 1) \times 10^{Qb}$  in magnitude, an invalid-operation exception is recognized, where p is the format precision and  $10^{Qb}$  is the requested quantum.

The expression,  $(10^p - 1) \times 10^{Qb}$ , specifies the largest magnitude that can be represented with the requested quantum in the format. A value larger than  $(10^p - 1) \times 10^{Qb}$  in magnitude will have more than p digits when the value is represented with the requested quantum.

- When both source operands are finite numbers, an invalid-operation exception can occur only if the requested quantum is smaller than the quantum of the third operand; and an inexact exception can occur only if the requested quantum is larger than the quantum of the third operand.
- The effective rounding methods listed in  $M_4$  as reserved are set aside for future extensions.
- Rounding for modifiers 8-15 is the same as for DFP rounding modes 0-7 (binary 000-111), respectively.

## REROUND

Mnemonic R<sub>1</sub>,R<sub>3</sub>,R<sub>2</sub>,M<sub>4</sub> [RRF]

Op Code	R <sub>3</sub>	M <sub>4</sub>	R <sub>1</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic	Op Code	Operands
RRDTR	'B3F7'	Long DFP
RRXTR	'B3FF'	Extended DFP

The third operand is rounded to the requested significance, and the result is placed at the first-operand location.

The requested significance, which specifies a number of DFP significant digits, is an unsigned binary integer and is in bit positions 58-63 of general register R<sub>2</sub>. The contents of bit positions 0-57 of general register R<sub>2</sub> are ignored.

When the third operand is a finite number, if the requested significance is zero, then the value of the third operand with the original quantum is placed at the first-operand location.

When the third operand is a finite number, if the requested significance is nonzero, and if the number of DFP significant digits of the third operand is equal to or less than the requested significance, then the value of the third operand with the original quantum is placed at the first-operand location.

When the third operand is a finite number, if the requested significance is nonzero, and if the number of DFP significant digits of the third operand is greater than the requested significance, then the third operand is rounded to the requested significance, and the result with the requested significance is placed at the first-operand location.

The third operand is rounded to the requested significance by rounding as specified by the modifier in the M<sub>4</sub> field:

### M<sub>4</sub> Effective Rounding Method

- 0 According to the current DFP rounding mode
- 1-7 Reserved
- 8 Round to nearest with ties to even
- 9 Round toward 0
- 10 Round toward +∞
- 11 Round toward -∞
- 12 Round to nearest with ties away from 0
- 13 Round to nearest with ties toward 0

**M<sub>4</sub> Effective Rounding Method**

- 14 Round away from 0  
 15 Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. When the modifier field is a reserved value, it is unpredictable which rounding method is performed.

The sign of the result, if numeric, is the same as the sign of the third operand.

This operation performs a functionally-constrained rounding, and does not recognize an underflow exception. No overflow condition can occur.

When the delivered value is exact, if the requested significance is zero, or if the requested significance is nonzero and the number of DFP significant digits of

the third operand is equal to or less than the requested significance, then the preferred quantum is the quantum of the third operand. When the delivered value is exact, if the requested significance is nonzero and the number of DFP significant digits of the third operand is greater than the requested significance, then the preferred quantum is the quantum that corresponds to the requested significance.

When the delivered value is inexact, the preferred quantum is the quantum that corresponds to the requested significance.

If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-26 for a detailed description of the results of this instruction.

Significance Comparison	Is $ Rp(c)  > (10^k - 1) \times 10^{Q_{max}}$ ?	Results for REROUND when the Third Operand (c) is							
		-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
k = 0	--	T(-∞)	T(c)	T(c)	T(c)	T(c)	T(+∞)	T(c)	Xi: T(c*)
k ≠ 0; k > m	--	T(-∞)	T(c)	T(c)	T(c)	T(c)	T(+∞)	T(c)	Xi: T(c*)
k ≠ 0; k = m	--	T(-∞)	T(c)	--	--	T(c)	T(+∞)	T(c)	Xi: T(c*)
k ≠ 0; k < m	No	T(-∞)	Rp(c)	--	--	Rp(c)	T(+∞)	T(c)	Xi: T(c*)
	Yes	T(-∞)	Xi:T(dNaN)	--	--	Xi:T(dNaN)	T(+∞)	T(c)	Xi: T(c*)

**Explanation:**

-- Not applicable.  
 \* The SNaN is converted to the corresponding QNaN and placed at the target operand location.  
 dNaN Default NaN.  
 Fn Nonzero finite numbers (includes both subnormal and normal).  
 k The requested significance.  
 m Number of DFP significant digits in the third operand (c).  
 Qmax Maximum right-units-view exponent.  
 Rp(c) The third operand (c) is rounded to the requested significance. The result is canonical and is represented with the preferred quantum.  
 |Rp(c)| The absolute value of Rp(c).  
 T(x) The canonical result x is placed at the target operand location. The result is canonical and, when it is a finite number, is represented with the preferred quantum.  
 Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-26. Results: REROUND

An invalid-operation exception is recognized when the resultant value cannot be represented in the target format with the requested significance. When the invalid-operation exception is recognized, and if the exception is disabled, the result is the default QNaN.

When an invalid-operation exception is recognized, the IEEE inexact exception is not recognized.

In the absence of an invalid-operation exception, if the result differs in value from the third operand, an IEEE inexact exception is recognized.

For RRXTR, the R<sub>1</sub> and R<sub>3</sub> fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:**

- Invalid operation
- Inexact

**Program Exceptions:**

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (RRXTR only)

**Programming Notes:**

1. REROUND and the round-to-prepare-for-shorter-precision rounding method can be used to simulate a DFP operation with a precision other than any supported format precision and with the effect of single rounding. The round-to-prepare-for-shorter-precision rounding method is used by the operation, and the desirable rounding method is used by the subsequent REROUND instruction.

2. When the rounded intermediate value is larger than  $(10^k - 1) \times 10^{Q_{max}}$  in magnitude, an invalid-operation exception is recognized, where k is the requested significance and  $10^{Q_{max}}$  is the largest quantum for the format.

The expression,  $(10^k - 1) \times 10^{Q_{max}}$ , specifies the largest magnitude that can be represented with the requested significance in the format. A value larger than  $(10^p - 1) \times 10^{Q_b}$  in magnitude will have a quantum larger than  $10^{Q_{max}}$  when the value is represented with the requested significance.

3. The effective rounding methods listed in M<sub>4</sub> as reserved are set aside for future extensions.
4. Rounding for modifiers 8-15 is the same as for DFP rounding modes 0-7 (binary 000-111), respectively.

## SHIFT SIGNIFICAND LEFT

Mnemonic	R <sub>1</sub> ,R <sub>3</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXF]						
OpCode	R <sub>3</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>	R <sub>1</sub>	////	OpCode	
0	8	12	16	20	32	36	40	47

Mnemonic	Op Code	Operands
SLDT	'ED40'	Long DFP
SLXT	'ED48'	Extended DFP

The significand of the third operand is shifted left the number of digits specified by the second-operand address, and the result is placed at the first-operand location.

Digits shifted out of the leftmost digit are lost. Zeros are supplied to the vacated positions on the right. The sign of the result is the same as the sign of the third operand.

For a finite number, all digits in the significand participate in the shift and the result is a finite number with the same biased exponent as the third operand and the shifted significand. For an infinity, all digits in the trailing significand participate in the shift, and the result is an infinity with the shifted trailing significand and a zero in the reserved field of the format. For a QNaN or SNaN, all digits in the payload participate in the shift and the result is a QNaN or SNaN, respectively, with the shifted payload and a zero in the reserved field of the format.

The second-operand address is not used to address data; its rightmost six bits indicate the number of digit positions to be shifted. The remainder of the address is ignored.

The preferred quantum is the quantum of the third operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the result are zeros, then the result is canonical; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For SLXT, the R<sub>1</sub> and R<sub>3</sub> fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (SLXT only)

**Programming Note:** Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

## SHIFT SIGNIFICAND RIGHT

Mnemonic	R <sub>1</sub> ,R <sub>3</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXF]					
OpCode	R <sub>3</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>	R <sub>1</sub>		OpCode
0	8	12	16	20	32	36	40
47							
Mnemonic	Op Code	<b>Operands</b>					
SRDT	'ED41'	Long DFP					
SRXT	'ED49'	Extended DFP					

The significand of the third operand is shifted right the number of digits specified by the second-operand address, and the result is placed at the first-operand location.

Digits shifted out of the rightmost digit are lost. Zeros are supplied to the vacated positions on the left. The sign of the result is the same as the sign of the third operand.

For a finite number, all digits in the significand participate in the shift and the result is a finite number with the same biased exponent as the third operand and the shifted significand. For an infinity, all digits in the trailing significand participate in the shift, and the result is an infinity with the shifted trailing significand and a zero in the reserved field of the format. For a QNaN or SNaN, all digits in the payload participate in the shift and the result is a QNaN or SNaN, respectively, with the shifted payload and a zero in the reserved field of the format.

The second-operand address is not used to address data; its rightmost six bits indicate the number of digit positions to be shifted. The remainder of the address is ignored.

The preferred quantum is the quantum of the third operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the result are zeros, then the result is canonical; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For SRXT, the R<sub>1</sub> and R<sub>3</sub> fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

**Condition Code:** The code remains unchanged.

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (SRXT only)

**Programming Note:** Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

## SUBTRACT

Mnemonic	R <sub>1</sub> ,R <sub>2</sub> ,R <sub>3</sub>	[RRR]		
Op Code	R <sub>3</sub>		R <sub>1</sub>	R <sub>2</sub>
0	16	20	24	28 31

Mnemonic	Op Code	Operands
SDTR	'B3D3'	Long DFP
SXTR	'B3DB'	Extended DFP

The third operand is subtracted from the second operand, and the difference is placed at the first-operand location.

The execution of SUBTRACT is identical to that of ADD, except that the third operand, if numeric, participates in the operation with its sign bit inverted. When the third operand is a NaN, it participates in the operation with its sign bit unchanged. See Figure 20-10 on page 20-17 for the detailed results of ADD.

When the delivered value is exact, the preferred quantum is the smaller quantum of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

For SXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

#### ***Resulting Condition Code:***

- 0 Result is zero
- 1 Result is less than zero
- 2 Result is greater than zero
- 3 Result is a NaN

#### ***IEEE Exceptions:***

- Invalid operation
- Overflow
- Underflow
- Inexact

#### ***Program Exceptions:***

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (SXTR only)

**Programming Note:** See the programming notes for ADD.

## **TEST DATA CLASS**

Mnemonic R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>) [RXE]

OpCode	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>		OpCode
0	8	12	16	20	32	40

<i>Mnemonic</i>	<i>Op Code</i>	<i>Operands</i>
TDCET	'ED50'	Short DFP
TDCDT	'ED54'	Long DFP
TDCXT	'ED58'	Extended DFP

The class and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of data class and sign. Bits 0-51 of the second-operand address are ignored.

As shown in Figure 20-27, DFP operands are divided into six classes: zero, subnormal, normal, infinity, quiet NaN, and signaling NaN:

<b>DFP data class</b>	<b>Bit used when sign is</b>	
	<b>+</b>	<b>-</b>
Zero	52	53
Subnormal	54	55
Normal	56	57
Infinity	58	59
Quiet NaN	60	61
Signaling NaN	62	63

Figure 20-27. Second-Operand-Address Bits for TEST DATA CLASS

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the class and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TDCXT, the R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

#### ***Resulting Condition Code:***

- 0 Selected bit is 0 (no match)

- 1 Selected bit is 1 (match)
- 2 --
- 3 --

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (TDCXT only)

#### Programming Notes:

1. TEST DATA CLASS provides a way to test an operand without risk of an exception or setting the IEEE flags.
2. The bits used to specify the combinations of data class and sign are not all the same for BFP and DFP. Specifically, BFP TEST DATA CLASS uses bits 54 and 55 for normal number, and bits 56 and 57 for subnormal number.

## TEST DATA GROUP

Mnemonic	R <sub>1</sub> ,D <sub>2</sub> (X <sub>2</sub> ,B <sub>2</sub> )	[RXE]
OpCode	R <sub>1</sub> X <sub>2</sub> B <sub>2</sub> D <sub>2</sub> ////////////// OpCode	0 8 12 16 20 32 40 47

Mnemonic	Op Code	Operands
TDGET	'ED51'	Short DFP
TGDDT	'ED55'	Long DFP
TDGXT	'ED59'	Extended DFP

The group and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of data group and sign. Bits 0-51 of the second-operand address are ignored.

TEST DATA GROUP is used to determine whether a finite number is safe. A finite number is safe if the exponent is neither maximum nor minimum, and the leftmost significand digit is zero.

Figure 20-28 on page 20-42 shows the data groups and the bit assignment. There are six data groups:

safe zero, zero with extreme exponent, nonzero with extreme exponent, safe nonzero, nonzero leftmost significand digit with nonextreme exponent, and special. The special group is defined for infinity and NaN. Depending on the model, subnormal with nonextreme exponent may be placed in the nonzero-with-extreme-exponent group or the safe-nonzero group.

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the group and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TDGXT, the R<sub>1</sub> field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

#### Resulting Condition Code:

- 0 Selected bit is 0 (no match)
- 1 Selected bit is 1 (match)
- 2 --
- 3 --

**IEEE Exceptions:** None.

#### Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (TDGXT only)

#### Programming Notes:

1. TEST DATA GROUP provides a way to test an operand without risk of an exception or setting the IEEE flags.
2. TEST DATA GROUP can be issued after an operation that produces a DFP result to quickly determine if the result is safe. For DFP results that are finite numbers, the result is safe if using a wider data format by the operation would have produced the same value and quantum. A safe result has two important characteristics: (1). the exponent is neither the maximum exponent nor the minimum exponent, and (2). the leftmost significand digit is zero.

3. In the absence of an IEEE exception, it does not mean that the result that is a finite number is safe. For example, multiplying  $100000 \times 10^3$  by  $100000 \times 10^5$  produces  $1000000 \times 10^{12}$  in the short format but produces  $100000000000 \times 10^8$  in a long format. These two results have the same value but different quantum. This case can be detected by TEST DATA GROUP by specifying the nonzero-leftmost-significand-digit-with-nonextreme-exponent group but cannot be detected by any IEEE exception.
4. TEST DATA GROUP may be used to test whether a nonzero finite number is safe by setting bits 58 and 59 of the second-operand address to ones.
5. TEST DATA GROUP may be used to test whether a nonzero finite number has reached the limit of the format precision but not the limit of the format range by setting bits 60 and 61 of the second-operand address to ones.
6. Subnormal with nonextreme exponent may be grouped with either the nonzero-with-extreme-exponent group or the safe-nonzero group. The program shouldn't depend on which group subnormal with nonextreme exponent is in.

DFP Operand	Exponent	LMD	Data Group	Bit used when sign is	
				+	-
Zero	Nonextreme	$z^1$	Safe zero	52	53
	Extreme	$z^1$	Zero with extreme exponent	54	55
Nonzero finite	Extreme	--	Nonzero with extreme exponent	56	57
	Nonextreme	$z$	Safe nonzero	58	59
	Nonextreme	$nz$	Nonzero leftmost significand digit with nonextreme exponent	60	61
Infinity or NaN	na	na	Special	62	63

Figure 20-28. Second-Operand-Address Bits for TEST DATA GROUP

DFP Operand	Exponent	LMD	Data Group	Bit used when sign is	
				+	-
<b>Explanation:</b>					
--	The result does not depend on this condition.				
$z^1$	This condition is true by virtue of the condition to the left of this column.				
Extreme	Maximum right-units-view (RUV) exponent, Qmax, or minimum right-units-view (RUV) exponent, Qmin.				
Nonextreme	$Q_{\text{max}} < \text{right-units-view (RUV) exponent} < Q_{\text{min}}$ .				
LMD	Leftmost significand digit.				
na	Not applicable.				
nz	Nonzero.				
z	Zero.				

Figure 20-28. Second-Operand-Address Bits for TEST DATA GROUP

## Densely Packed Decimal (DPD)

### Decimal-to-DPD Mapping

The mapping of a 3-digit decimal number (000 - 999) to a 10-bit value, called a declet is shown in Figure 20-29 on page 20-45. The DPD entries are shown in hexadecimal. The first two digits of the decimal number are shown in the leftmost column and the third digit along the top row. The table is split into two halves, with the right half being a continuation of the left half.

### DPD-to-Decimal Mapping

The mapping of the 10-bit declet to a 3-digit decimal number is shown in Figure 20-30 on page 20-46. The 10-bit declet value is split into a 6-bit index shown in the left column and a 4-bit index shown along the top row, both represented in hexadecimal. The values marked with an asterisk are results mapped from noncanonical declets and are explained further in the following section.

### Summary of Noncanonical Declets

Of the 1024 possible declets, 1000 canonical declets are produced in resultant DFP operands, while 24 noncanonical declets are not produced as DFP results, but are accepted in source DFP operands.

The following table shows the 24 noncanonical declets, the decimal value that each maps to, and the

corresponding canonical declet that this decimal value maps to.

Noncanonical Declets (Hex)			Map To Decimal Value	Canonical Declets (Hex)

This appendix (except for the examples for FIND LEFTMOST ONE, ROTATE THEN EXCLUSIVE OR SELECTED BITS, ROTATE THEN INSERT SELECTED BITS, ROTATE THEN OR SELECTED BITS, and changes in the terminology for signed-packed decimal and unsigned-packed decimal) is the same as in *Enterprise Systems Architecture/390 Principles of Operation*, SA22-7201; it has not been revised to show the enlargement of register sizes or the 64-bit addressing mode.

# Number Representation

# Binary Integers

# Signed Binary Integers

Signed binary integers are most commonly represented as halfwords (16 bits) or words (32 bits). In both lengths, the leftmost bit (bit 0) is the sign of the number. The remaining bits (bits 1-15 for halfwords and 1-31 for words) are used to specify the magnitude of the number. Binary integers are also referred to as fixed-point numbers, because the radix point (binary point) is considered to be fixed at the right, and any scaling is done by the programmer.

Positive binary integers are in true binary notation with a zero sign bit. Negative binary integers are in two's-complement notation with a one bit in the sign

position. In all cases, the bits between the sign bit and the leftmost significant bit of the integer are the same as the sign bit (that is, all zeros for positive numbers, all ones for negative numbers).

Negative binary integers are formed in two's-complement notation by inverting each bit of the positive binary integer and adding one. As an example using the halfword format, the binary number with the decimal value +26 is made negative (-26) in the following manner:

+26	0 000 0000 0001 1010
Invert	1 111 1111 1110 0101
Add 1	1
<hr/>	
-26	1 111 1111 1110 0110
(Two's complement form)	
(S is the sign bit.)	

This is equivalent to subtracting the number:

00000000 00011010  
from 1 00000000 00000000

Negative binary integers are changed to positive in the same manner.

The following addition examples illustrate two's-complement arithmetic and overflow conditions. Only eight bit positions are used.

1.	$+57 = 0011\ 1001$	
	$+35 = 0010\ 0011$	
	<hr/>	
	$+92 = 0101\ 1100$	
2.	$+57 = 0011\ 1001$	
	$-35 = 1101\ 1101$	
	<hr/>	
	$+22 = 0001\ 0110$	No overflow – carry into leftmost position and carry out
3.	$+35 = 0010\ 0011$	
	$-57 = 1100\ 0111$	
	<hr/>	
	$-22 = 1110\ 1010$	Sign change only – no carry into leftmost position and no carry out
4.	$-57 = 1100\ 0111$	
	$-35 = 1101\ 1101$	
	<hr/>	
	$-92 = 1010\ 0100$	No overflow – carry into leftmost position and carry out
5.	$+57 = 0011\ 1001$	
	$+92 = 0101\ 1100$	
	<hr/>	
	$+149 = *1001\ 0101$	*Overflow – carry into leftmost position, no carry out
6.	$-57 = 1100\ 0111$	
	$-92 = 1010\ 0100$	
	<hr/>	
	$-149 = *0110\ 1011$	*Overflow – no carry into leftmost position but carry out

The presence or absence of an overflow condition may be recognized from the carries:

- There is no overflow:

1. If there is no carry into the leftmost bit position and no carry out (examples 1 and 3).

2. If there is a carry into the leftmost position and also a carry out (examples 2 and 4).

- There is an overflow:

1. If there is a carry into the leftmost position but no carry out (example 5).

2. If there is no carry into the leftmost position but there is a carry out (example 6).

The following are 16-bit signed binary integers. The first is the maximum positive 16-bit binary integer. The last is the maximum negative 16-bit binary integer (the negative 16-bit binary integer with the greatest absolute value).

$2^{15}-1 =$	32,767 =	0 111 1111 1111 1111
$2^0 ==$	1 =	0 000 0000 0000 0001
$0 =$	0 =	0 000 0000 0000 0000
$-2^0 =$	-1 =	1 111 1111 1111 1111
$-2^{15} =$	-32,768 =	1 000 0000 0000 0000

Figure A-1 illustrates several 32-bit signed binary integers arranged in descending order. The first is the maximum positive binary integer that can be represented by 32 bits, and the last is the maximum negative binary integer that can be represented by 32 bits.

$2^{31}-1 =$	2 147 483 647	= 0 111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111

Figure A-1. 32-Bit Signed Binary Integers

### Unsigned Binary Integers

Certain instructions, such as ADD LOGICAL, treat

binary integers as unsigned rather than signed. Unsigned binary integers have the same format as

signed binary integers, except that the leftmost bit is interpreted as another numeric bit rather than a sign bit. There is no complement notation because all unsigned binary integers are considered positive.

The following examples illustrate the addition of unsigned binary integers. Only eight bit positions are used. The examples are numbered the same as the corresponding examples for signed binary integers.

$$\begin{array}{r} 57 = 0011\ 1001 \\ 35 = 0010\ 0011 \\ \hline \end{array}$$

$$92 = 0101\ 1100$$

$$\begin{array}{r} 57 = 0011\ 1001 \\ 221 = 1101\ 1101 \\ \hline \end{array}$$

$$278 = *0001\ 0110 \text{ *Carry out of leftmost position}$$

$$\begin{array}{r} 35 = 0010\ 0011 \\ 199 = 1100\ 0111 \\ \hline \end{array}$$

$$234 = 1110\ 1010$$

$2^{32}-1 = 4\ 294\ 967\ 295 =$	<code>1111 1111 1111 1111 1111 1111 1111 1111</code>
$2^{31} = 2\ 147\ 483\ 648 =$	<code>1000 0000 0000 0000 0000 0000 0000 0000</code>
$2^{31}-1 = 2\ 147\ 483\ 647 =$	<code>0111 1111 1111 1111 1111 1111 1111 1111</code>
$2^{16} = 65\ 536 =$	<code>0000 0000 0000 0001 0000 0000 0000 0000</code>
$2^0 = 1 =$	<code>0000 0000 0000 0000 0000 0000 0000 0001</code>
$0 = 0 =$	<code>0000 0000 0000 0000 0000 0000 0000 0000</code>

Figure A-2. 32-Bit Unsigned Binary Integers

## Decimal Integers

Decimal integers consist of one or more decimal digits and a sign. Each digit and the sign are represented by a 4-bit code. The decimal digits are in binary-coded decimal (BCD) form, with the values 0-9 encoded as 0000-1001. The sign is usually represented as 1100 (C hex) for plus and 1101 (D hex) for minus. These are the preferred sign codes, which are generated by the machine for the results of decimal-arithmetic operations. There are also several alternate sign codes (1010, 1110, and 1111 for plus; 1011 for minus). The alternate sign codes are accepted by the machine as valid in source operands but are not generated for results.

Decimal integers may have different lengths, from one to 16 bytes. Of the many decimal formats, only

$$\begin{array}{r} 199 = 1100\ 0111 \\ 221 = 1101\ 1101 \\ \hline \end{array}$$

$$420 = *1010\ 0100 \text{ *Carry out of leftmost position}$$

$$\begin{array}{r} 57 = 0011\ 1001 \\ 92 = 0101\ 1100 \\ \hline \end{array}$$

$$149 = 1001\ 0101$$

$$\begin{array}{r} 199 = 1100\ 0111 \\ 164 = 1010\ 0100 \\ \hline \end{array}$$

$$363 = *0110\ 1011 \text{ *Carry out of leftmost position}$$

A carry out of the leftmost bit position may or may not imply an overflow, depending on the application.

Figure A-2 illustrates several 32-bit unsigned binary integers arranged in descending order.

two will be considered here: signed-packed-decimal and zoned. In the signed-packed-decimal format, each byte contains two decimal digits, except for the rightmost byte, which contains the sign code in the right half. For decimal arithmetic, the number of decimal digits in the signed-packed-decimal format can vary from one to 31. Because decimal integers must consist of whole bytes and there must be a sign code on the right, the number of decimal digits in this format is always odd. If an even number of significant digits is desired, a leading zero must be inserted on the left.

In the zoned format, each byte consists of a decimal digit on the right and the zone code 1111 (F hex) on the left, except for the rightmost byte where the sign code replaces the zone code. Thus, a decimal integer in the zoned format can have from one to 16 digits. The zoned format may be used directly for input

and output in the extended binary-coded-decimal interchange code (EBCDIC), except that the sign must be separated from the rightmost digit and handled as a separate character. For positive (unsigned) numbers, however, the sign can simply be represented by the zone code of the rightmost digit because the zone code is one of the acceptable alternate codes for plus.

In either format, negative decimal integers are represented in true notation with a separate sign. As for binary integers, the radix point (decimal point) of decimal integers is considered to be fixed at the right, and any scaling is done by the programmer.

The following are some examples of decimal integers shown in hexadecimal notation:

<b>Decimal Value</b>	<b>Signed Packed Format</b>	<b>Zoned Format</b>
+123	12 3C or 12 3F	F1 F2 C3 or F1 F2 F3
-4321	04 32 1D	F4 F3 F2 D1
+000050	00 00 05 0C or 00 00 05 0F	F0 F0 F0 F0 F5 C0 or F0 F0 F0 F0 F5 F0
-7	7D	D7
00000	00 00 0C or 00 00 0F	F0 F0 F0 F0 C0 or F0 F0 F0 F0 F0

Under some circumstances, a zero with a minus sign (negative zero) is produced. For example, the multiplicand:

00 12 3D (-123)

times the multiplier:

0C (+0)

generates the product:

00 00 0D (-0)

because the product sign follows the algebraic rule of signs even when the value is zero. A negative zero,

however, is equivalent to a positive zero in that they compare equal in a decimal comparison.

## Hexadecimal-Floating-Point Numbers

A hexadecimal-floating-point (HFP) number is expressed as a hexadecimal fraction multiplied by a separate power of 16. The term floating point indicates that the placement, or scaling, is automatically maintained by the machine.

The part of an HFP number which represents the significant digits of the number is called the fraction. A second part specifies the power (exponent) to which 16 is raised and indicates the location of the radix point of the number. The fraction and exponent may be represented by 32 bits (short format), 64 bits (long format), or 128 bits (extended format).

Short HFP Number

S	Characteristic	6-Digit Fraction	
0 1		8	31

Long HFP Number

Word

0	S	Characteristic	14-Digit Fraction	
0 1		8	31	
1	14-Digit Fraction (continued)			
32			63	

Extended HFP Number

Word

0	S	High-Order Characteristic	Leftmost 14 Digits of 28-Digit Fraction	
0 1		8	31	
1	Leftmost 14 Digits of 28-Digit Fraction (continued)			
32			63	
2	S	Low-Order Characteristic	Rightmost 14 Digits of 28-Digit Fraction	
64		72	95	
3	Rightmost 14 Digits of 28-Digit Fraction (continued)			
96			127	

An HFP number has two signs: one for the fraction and one for the exponent. The fraction sign, which is also the sign of the entire number, is the leftmost bit of each format (0 for plus, 1 for minus). The numeric part of the fraction is in true notation regardless of the sign. The numeric part is contained in bits 8-31 for the short format, in bits 8-63 for the long format, and in bits 8-63 followed by bits 72-127 for the extended format.

The exponent sign is obtained by expressing the exponent in excess-64 notation; that is, the exponent is added as a signed number to 64. The resulting number is called the characteristic. It is located in bits 1-7 for all formats. The characteristic can vary from 0 to 127, permitting the exponent to vary from -64 through 0 to +63. This provides a scale multiplier in the range of  $16^{-64}$  to  $16^{+63}$ . A nonzero fraction, if normalized, has a value less than one and greater than or equal to 1/16, so that the range covered by the magnitude M of a normalized floating-point number is:

$$16^{-65} \leq M < 16^{63}$$

In decimal terms:

$$16^{-65} \text{ is approximately } 5.4 \times 10^{-79}$$

$$16^{63} \text{ is approximately } 7.2 \times 10^{75}$$

1.0	$= +1/16 \times 16^1$	$= 0\ 100\ 0001\ 0001\ 0000\ 0000\ 0000\ 0000\ 0000_2$
0.5	$= +8/16 \times 16^0$	$= 0\ 100\ 0000\ 1000\ 0000\ 0000\ 0000\ 0000\ 0000_2$
1/64	$= +4/16 \times 16^{-1}$	$= 0\ 011\ 1111\ 0100\ 0000\ 0000\ 0000\ 0000\ 0000_2$
0.0	$= +0 \times 16^{-64}$	$= 0\ 000\ 0000\ 0000\ 0000\ 0000\ 0000\ 0000\ 0000_2$
-15.0	$= -15/16 \times 16^1$	$= 1\ 100\ 0001\ 1111\ 0000\ 0000\ 0000\ 0000\ 0000_2$
$5.4 \times 10^{-79}$	$\approx +1/16 \times 16^{-64}$	$= 0\ 000\ 0000\ 0001\ 0000\ 0000\ 0000\ 0000\ 0000_2$
$7.2 \times 10^{75}$	$\approx (1-16^{-6}) \times 16^{63}$	$= 0\ 111\ 1111\ 1111\ 1111\ 1111\ 1111\ 1111_2$

Figure A-3. Normalized Short Hexadecimal-Floating-Point Numbers

## Conversion Example

Convert the decimal number 59.25 to a short HFP number. (In another appendix are tables for the conversion of hexadecimal and decimal integers and fractions.)

1. The number is separated into a decimal integer and a decimal fraction.

$$59.25 = 59 \text{ plus } 0.25$$

More precisely,

In the short format:

$$16^{-65} \leq M \leq (1 - 16^{-6}) \times 16^{63}$$

In the long format:

$$16^{-65} \leq M \leq (1 - 16^{-14}) \times 16^{63}$$

In the extended format:

$$16^{-65} \leq M \leq (1 - 16^{-28}) \times 16^{63}$$

Within a given fraction length (6, 14, or 28 digits), an HFP operation will provide the greatest precision if the fraction is normalized. A fraction is normalized when the leftmost digit (bit positions 8, 9, 10, and 11) is nonzero. It is unnormalized if the leftmost digit contains all zeros.

If normalization of the operand is desired, the HFP instructions that provide automatic normalization are used. This automatic normalization is accomplished by left-shifting the fraction (four bits per shift) until a nonzero digit occupies the leftmost digit position. The characteristic is reduced by one for each digit shifted.

Figure A-3 illustrates sample normalized short HFP numbers. The last two numbers represent the smallest and the largest positive normalized numbers.

2. The decimal integer is converted to its hexadecimal representation.

$$59_{10} = 3B_{16}$$

3. The decimal fraction is converted to its hexadecimal representation.

$$0.25_{10} = 0.4_{16}$$

4. The integral and fractional parts are combined and expressed as a fraction times a power of 16 (exponent).

$$3B.4_{16} = 0.3B4_{16} \times 16^2$$

5. The characteristic is developed from the exponent and converted to binary.

$$\begin{array}{l} \text{base + exponent} = \text{characteristic} \\ 64 + 2 = 66 = 1000010 \end{array}$$

6. The fraction is converted to binary and grouped hexadecimally.

$$.3B4_{16} = .0011\ 1011\ 0100$$

7. The characteristic and the fraction are stored in the short format. The sign position contains the sign of the fraction.

S	Char	Fraction
0	1000010	0011 1011 0100 0000 0000 0000

Examples of instruction sequences that may be used to convert between signed binary integers and HFP numbers are shown in “Hexadecimal-Floating-Point-Number Conversion” on page A-44.

## Instruction-Use Examples

The following examples illustrate the use of many of the unprivileged instructions. Before studying one of these examples, the reader should consult the instruction description.

The instruction-use examples are written principally for assembler-language programmers, to be used in conjunction with the appropriate assembler-language publications.

Most examples present one particular instruction, both as it is written in an assembler-language statement and as it appears when assembled in storage (machine format).

## Machine Format

All machine-format values are given in hexadecimal notation unless otherwise specified. Storage addresses are also given in hexadecimal. Hexadecimal operands are shown converted into binary, decimal, or both if such conversion helps to clarify the example for the reader.

## Assembler-Language Format

In assembler-language statements, registers and lengths are presented in decimal. Displacements, immediate operands, and masks may be shown in decimal, hexadecimal, or binary notation; for example, 12, X'C', and B'1100' represent the same value. Whenever the value in a register or storage location is referred to as “not significant,” this value is replaced during the execution of the instruction.

When SS-format instructions are written in the assembler language, lengths are given as the total number of bytes in the field. This differs from the machine definition, in which the length field specifies the number of bytes to be added to the field address to obtain the address of the last byte of the field. Thus, the machine length is one less than the assembler-language length. The assembler program automatically subtracts one from the length specified when the instruction is assembled.

In some of the examples, symbolic addresses are used in order to simplify the examples. In assembler-language statements, a symbolic address is represented as a mnemonic term written in all capitals, such as FLAGS, which may denote the address of a storage location containing data or program-control information. When symbolic addresses are used, the assembler supplies actual base and displacement values according to the programmer’s specifications. Therefore, the actual values for base and displacement are not shown in the assembler-language format or in the machine-language format. For assembler-language formats, in the labels that designate instruction fields, the letter “S” is used to indicate the combination of base and displacement fields for an operand address. (For example, S2 represents the combination of B2 and D2.) In the machine-language format, the base and displacement address components are shown as asterisks (\*\*\*)�.

## Addressing Mode in Examples

Except where otherwise specified, the examples assume the 24-bit addressing mode.

## General Instructions

(See Chapter 7, “General Instructions” for a complete description of the general instructions.)

## ADD HALFWORD (AH)

The ADD HALFWORD instruction algebraically adds the contents of a two-byte field in storage to the contents of a register. The storage operand is expanded to 32 bits after it is fetched and before it is used in the add operation. The expansion consists in propagating the leftmost (sign) bit 16 positions to the left. For example, assume that the contents of storage locations 2000-2001 are to be added to register 5. Initially:

Register 5 contains  $00\ 00\ 00\ 19 = 25_{10}$ .

Storage locations 2000-2001 contain FF FE =  $-2_{10}$ .

Register 12 contains 00 00 18 00.

Register 13 contains 00 00 01 50.

The format of the required instruction is:

### Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
4A	5	D	C	6B0

### Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

AH 5,X'6B0'(13,12)

After the instruction is executed, register 5 contains 00 00 00 17 =  $23_{10}$ . Condition code 2 is set to indicate a result greater than zero.

## AND (N, NC, NI, NR)

When the Boolean operator AND is applied to two bits, the result is one when both bits are one; otherwise, the result is zero. When two bytes are ANDed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of ANDing two bytes:

First-operand byte: 0011 0101<sub>2</sub>  
Second-operand byte: 0101 1100<sub>2</sub>

Result byte: 0001 0100<sub>2</sub>

### NI Example

A frequent use of the AND instruction is to set a particular bit to zero. For example, assume that storage location 4891 contains 0100 0011<sub>2</sub>. To set the rightmost bit of this byte to zero without affecting the other bits, the following instruction can be used (assume that register 8 contains 00 00 48 90):

### Machine Format

Op Code	I <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>
94	FE	8	001

### Assembler Format

Op Code D<sub>1</sub>(B<sub>1</sub>),I<sub>2</sub>

NI 1(8),X'FE'

When this instruction is executed, the byte in storage is ANDed with the immediate byte (the I<sub>2</sub> field of the instruction):

Location 4891: 0100 0011<sub>2</sub>  
Immediate byte: 1111 1110<sub>2</sub>

Result: 0100 0010<sub>2</sub>

The resulting byte, with bit 7 set to zero, is stored back in location 4891. Condition code 1 is set.

## Linkage Instructions (BAL, BALR, BAS, BASR, BASSM, BSM)

Four unprivileged instructions (BRANCH AND LINK, BRANCH AND SAVE, BRANCH AND SAVE AND SET MODE, and BRANCH AND SET MODE) are available, together with the unconditional branch (BRANCH ON CONDITION with a mask of 15), to provide linkage between subroutines. BRANCH AND LINK (BAL or BALR) is provided primarily for compatibility with programs written for System/370; BRANCH AND SAVE (BAS or BASR) is recommended instead for programs which are to be executed using ESA/370. The instructions BRANCH AND SAVE AND SET MODE (BASSM) and BRANCH AND SET MODE (BSM) provide subroutine linkage together with switching between the 24-bit and the 31-bit addressing modes. The use of these instructions is discussed in a programming note at the end of "Subroutine Linkage without the Linkage Stack." (See also the semiprivileged instruction BRANCH AND STACK.)

The following example compares the operation of these instructions and of the unconditional-branch instruction BRANCH ON CONDITION (BC or BCR with a mask of 15). Assume that each instruction in turn is located at the current instruction address, ready to be executed next. For the first set of examples, the addressing-mode bit, PSW bit 32, is initially zero (24-bit addressing in effect). For the second set, PSW bit 32 is initially one (31-bit addressing). Assume also that general register 5 is to receive the linkage information, and that general register 6 contains the branch address.

The format of the BALR instruction is:

Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
05	5	6

Assembler Format

Op Code R<sub>1</sub>, R<sub>2</sub>

BALR 5,6

The other linkage instructions in the RR format have the same format but different op codes:

BASR 0D  
BASSM 0C  
BSM 0B

For comparison with the RR-format instructions, the results of two RX-format instructions are also shown.

The format of the BAL instruction is:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
45	5	0	6	000

Assembler Format

Op Code R<sub>1</sub>, D<sub>2</sub>(X<sub>2</sub>, B<sub>2</sub>)

BAL 5,0(0,6)

The BAS instruction has the same format, but the op code is 4D.

The BCR instruction specifies only one register:

Machine Format

Op Code	M <sub>1</sub>	R <sub>2</sub>
07	F	6

Assembler Format

Op Code M<sub>1</sub>, R<sub>2</sub>

BCR 15,6

Assume that:

Register 5 contains BB BB BB BB.

Register 6 contains 82 46 8A CE.

PSW bits 32-63 contain

00 00 10 D6 (for 24-bit addressing).  
80 00 10 D6 (for 31-bit addressing).

Condition code is 01<sub>2</sub>.

Program mask is 1100<sub>2</sub>.

The effect of executing each instruction in turn is as follows:

#### 24-Bit Mode Initially

Instruction	Register 5	PSW (32-63)
Before	BB BB BB BB	00 00 10 D6
BCR 15,6	BB BB BB BB	00 46 8A CE
BAL 5,0(0,6)	9C 00 10 DA	00 46 8A CE
BAS 5,0(0,6)	00 00 10 DA	00 46 8A CE
BALR 5,6	5C 00 10 D8	00 46 8A CE
BASR 5,6	00 00 10 D8	00 46 8A CE
BASSM 5,6	00 00 10 D8	82 46 8A CE
BSM 5,6	3B BB BB BB	82 46 8A CE

#### 31-Bit Mode Initially

Instruction	Register 5	PSW (32-63)
Before	BB BB BB BB	80 00 10 D6
BCR 15,6	BB BB BB BB	82 46 8A CE
BAL 5,0(0,6)	80 00 10 DA	82 46 8A CE
BAS 5,0(0,6)	80 00 10 DA	82 46 8A CE
BALR 5,6	80 00 10 D8	82 46 8A CE
BASR 5,6	80 00 10 D8	82 46 8A CE
BASSM 5,6	80 00 10 D8	82 46 8A CE
BSM 5,6	BB BB BB BB	82 46 8A CE

Note that a value of zero in the R<sub>2</sub> field of any of the RR-format instructions indicates that the branching function is not to be performed; it does not refer to register 0. Likewise, a value of zero in the R<sub>1</sub> field of the BSM instruction indicates that the old value of

PSW bit 32 is not to be saved and that register 0 is to be left unchanged. Register 0 can be designated by the R<sub>1</sub> field of instructions BAL, BALR, BAS, BASR, and BASSM, however. In the RX-format branch instructions, branching occurs independent of whether there is a value of zero in the B<sub>2</sub> field or X<sub>2</sub> field of the instruction. However, when the field is zero, instead of using the contents of general register 0, a value of zero is used for that component of address generation.

**Programming Note:** It should be noted that execution of BAL in the 24-bit addressing mode results in bit 0 of register 5 being set to one. This is because the ILC for an RX-format instruction is 10. This is the only case in which bit zero of the return register does not correctly reflect the addressing mode of the caller. Thus, BSM may be used to return for BALR, BAS, BASR, and BASSM in both the 24-bit and the 31-bit addressing modes, but it cannot be used to return if the program was called by using BAL in the 24-bit addressing mode.

### Other BALR and BASR Examples

The BALR or BASR instruction with the R<sub>2</sub> field set to zero may be used to load a register for use as a base register. For example, in the assembler language, the two statements:

```
BALR    15,0  
USING   *,15
```

or

```
BASR    15,0  
USING   *,15
```

indicate that the address of the next sequential instruction following the BALR or BASR instruction will be placed in register 15, and that the assembler may use register 15 as a base register until otherwise instructed. (The USING statement is an “assembler instruction” and is thus not a part of the object program.)

## BRANCH AND STACK (BAKR)

The semiprivilaged BRANCH AND STACK instruction facilitates linkage between subroutines by saving status in a linkage-stack state entry (sometimes called a branch state entry to distinguish it from a program-call state entry). When BRANCH AND STACK has been used, the return from the called

program is made by means of the PROGRAM RETURN instruction. PROGRAM RETURN restores access registers 2-14, general registers 2-14, and the PSW with values saved in the state entry, except that it leaves the PER mask unchanged and sets the condition code to an unpredictable value. The use of BRANCH AND STACK is discussed in “Branching Using the Linkage Stack” on page 5-69.

BRANCH AND STACK can be used to perform a calling linkage, or it can be used at or near the entry point of the called program, depending on whether the R<sub>1</sub> field of the instruction is zero or nonzero, respectively. If the R<sub>1</sub> field is zero, bits 32-63 of the PSW saved in the state entry indicate the current addressing mode (24-bit or 31-bit) and the address of the next sequential instruction after the BRANCH AND STACK instruction or an EXECUTE instruction. If the R<sub>1</sub> field is nonzero, bits 32-63 of the PSW saved in the state entry are set with a value generated from the contents of general register R<sub>1</sub>; bit 32 of the PSW is set equal to bit 0 of the register, and bits 1-31 of the PSW are set with an address generated from bits 1-31 of the register under the control of bit 0 of the register. Bits 32-63 of the PSW saved in the state entry are referred to in the following examples as the return value.

The branch address for the instruction is generated from the contents of general register R<sub>2</sub> under the control of the current addressing mode. Bit 0 of general register R<sub>2</sub> does not affect the operation. If the R<sub>2</sub> field of the instruction is zero, the operation is performed without branching.

In addition to saving a complete PSW (except with an unpredictable PER mask) in the state entry, BRANCH AND STACK saves the new value of bits 32-63 of the current PSW in the state entry. Bits 32-63 are referred to in the following examples as the branch value.

The following examples contain cases in which bit 32 of the current PSW is either zero or one (24-bit or 31-bit addressing) before BRANCH AND STACK is executed and in which bit 0 of the general register designated by a nonzero R<sub>1</sub> or R<sub>2</sub> field is either zero or one.

### BAKR Example 1

This example shows BAKR used in a calling program. BAKR performs a branch, and the return is to be to the next sequential instruction.

The format of the BAKR instruction is:

Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
B240	0	6

Assembler Format

Op Code	R <sub>1</sub> , R <sub>2</sub>
BAKR	0,6

Assume four cases of initial values, as follows:

PSW (32-63)	Register 6
1. 00 00 10 D6	02 46 8A CE
2. 00 00 10 D6	82 46 8A CE
3. 80 00 10 D6	02 46 8A CE
4. 80 00 10 D6	82 46 8A CE

The results in the four cases are as follows:

Return Value	Branch Value and PSW (32-63)
1. 00 00 10 DA	00 46 8A CE
2. 00 00 10 DA	00 46 8A CE
3. 80 00 10 DA	82 46 8A CE
4. 80 00 10 DA	82 46 8A CE

## BAKR Example 2

This example shows BAKR used in a called program. BAKR does not perform a branch, and the return is to be as specified in general register R<sub>1</sub>.

The format of the BAKR instruction is:

Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
B240	5	0

Assembler Format

Op Code	R <sub>1</sub> , R <sub>2</sub>
BAKR	5,0

Assume four cases of initial values, as follows:

Register 5	PSW (32-63)
1. 04 00 10 D6	00 46 8A CE
2. 04 00 10 D6	82 46 8A CE

3. 84 00 10 D6	00 46 8A CE
4. 84 00 10 D6	82 46 8A CE

The results in the four cases are as follows:

Return Value	Branch Value and PSW (32-63)
1. 00 00 10 D6	00 46 8A D2
2. 00 00 10 D6	82 46 8A D2
3. 84 00 10 D6	00 46 8A D2
4. 84 00 10 D6	82 46 8A D2

## BAKR Example 3

This example shows BAKR used in a called program. BAKR performs a branch, and the return is to be as specified in general register R<sub>1</sub>.

The format of the BAKR instruction is:

Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
B240	5	6

Assembler Format

Op Code	R <sub>1</sub> , R <sub>2</sub>
BAKR	5,6

Assume eight cases of initial values, as follows:

Register 5	Register 6	PSW (32-63)
1. 04 00 10 D6	06 99 99 00	00 46 8A CE
2. 04 00 10 D6	06 99 99 00	82 46 8A CE
3. 04 00 10 D6	86 99 99 00	00 46 8A CE
4. 04 00 10 D6	86 99 99 00	82 46 8A CE
5. 84 00 10 D6	06 99 99 00	00 46 8A CE
6. 84 00 10 D6	06 99 99 00	82 46 8A CE
7. 84 00 10 D6	86 99 99 00	00 46 8A CE
8. 84 00 10 D6	86 99 99 00	82 46 8A CE

The results in the eight cases are as follows:

Return Value	Branch Value and PSW (32-63)
1. 00 00 10 D6	00 99 99 00
2. 00 00 10 D6	86 99 99 00
3. 00 00 10 D6	00 99 99 00
4. 00 00 10 D6	86 99 99 00
5. 84 00 10 D6	00 99 99 00
6. 84 00 10 D6	86 99 99 00
7. 84 00 10 D6	00 99 99 00
8. 84 00 10 D6	86 99 99 00

## BRANCH ON CONDITION (BC, BCR)

The BRANCH ON CONDITION instruction tests the condition code to see whether a branch should or should not occur. The branch occurs only if the current condition code corresponds to a one bit in a mask specified by the instruction.

Condition Code	Instruction (Mask) Bit	Mask Value
0	8	8
1	9	4
2	10	2
3	11	1

For example, assume that an ADD (A or AR) operation has been performed and that a branch to address 6050 is desired if the sum is zero or less (condition code is 0 or 1). Also assume:

Register 10 contains 00 00 50 00.

Register 11 contains 00 00 10 00.

The RX form of the instruction performs the required test (and branch if necessary) when written as:

Machine Format

Op Code	M <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
47	C	B	A	050

Assembler Format

Op Code M<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

---

BC 12,X'50'(11,10)

A mask of 12<sub>10</sub> means that there are ones in instruction bits 8 and 9 and zeros in bits 10 and 11, so that branching takes place when the condition code is either 0 or 1.

A mask of 15 would indicate a branch on any condition (an unconditional branch). A mask of zero would indicate that no branch is to occur (a no-operation).

(See also “Linkage Instructions (BAL, BALR, BAS, BASR, BASSM, BSM)” on page A-8 for an example of the BCR instruction.)

## BRANCH ON COUNT (BCT, BCTR)

The BRANCH ON COUNT instruction is often used to execute a program loop for a specified number of times. For example, assume that the following represents some lines of coding in an assembler-language program:

```
:
LUPE AR 8,1
:
BACK BCT 6,LUPE
:
```

where register 6 contains 00 00 00 03 and the address of LUPE is 6826. Assume that, in order to address this location, register 10 is used as a base register and contains 00 00 68 00.

The format of the BCT instruction is:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
46	6	0	A	026

Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

---

BCT 6,X'26'(0,10)

The effect of the coding is to execute three times the loop defined by the instructions labeled LUPE through BACK, while register 6 is decremented from three to zero.

## BRANCH ON INDEX HIGH (BXH)

### BXH Example 1

The BRANCH ON INDEX HIGH instruction is an index-incrementing and loop-controlling instruction that causes a branch whenever the sum of an index value and an increment value is greater than some compare value. For example, assume that:

Register 4 contains 00 00 00 8A = 138<sub>10</sub> = the index.

Register 6 contains 00 00 00 02 = 2<sub>10</sub> = the increment.

Register 7 contains 00 00 00 AA = 170<sub>10</sub> = the compare value.

Register 10 contains 00 00 71 30 = the branch address.

The format of the BXH instruction is:

#### Machine Format

Op Code	R <sub>1</sub>	R <sub>3</sub>	B <sub>2</sub>	D <sub>2</sub>
86	4	6	A	000

#### Assembler Format

Op Code R<sub>1</sub>,R<sub>3</sub>,D<sub>2</sub>(B<sub>2</sub>)

BXH 4,6,0(10)

When the instruction is executed, first the contents of register 6 are added to register 4, second the sum is compared with the contents of register 7, and third the decision whether to branch is made. After execution:

Register 4 contains 00 00 00 8C = 140<sub>10</sub>.

Registers 6 and 7 are unchanged.

Since the new value in register 4 is not yet greater than the value in register 7, the branch to address 7130 is not taken. Repeated use of the instruction will eventually cause the branch to be taken when the value in register 4 reaches 172<sub>10</sub>.

### BXH Example 2

When the register used to contain the increment is odd, that register also becomes the compare-value register. The following assembler-language subroutine illustrates how this may be used to search a table.

Table	
2 Bytes	2 Bytes
ARG1	FUNC1
ARG2	FUNC2
ARG3	FUNC3
ARG4	FUNC4
ARG5	FUNC5
ARG6	FUNC6

Assume that:

Register 8 contains the search argument.

Register 9 contains the width of the table in bytes (00 00 00 04).

Register 10 contains the length of the table in bytes (00 00 00 18).

Register 11 contains the starting address of the table.

Register 14 contains the return address to the main program.

As the following subroutine is executed, the argument in register 8 is successively compared with the arguments in the table, starting with argument 6 and working backward to argument 1. If an equality is found, the corresponding function replaces the argument in register 8. If an equality is not found, zero replaces the argument in register 8.

SEARCH	LNR	9,9
NOTEQUAL	BXH	10,9,LOOP
NOTFOUND	SR	8,8
	BCR	15,14
LOOP	CH	8,0(10,11)
	BC	7,NOTEQUAL
	LH	8,2(10,11)
	BCR	15,14

The first instruction (LNR) causes the value in register 9 to be made negative. After execution of this instruction, register 9 contains FF FF FF FC = -4<sub>10</sub>. Considering the case when no equality is found, the BXH instruction will be executed seven times. Each time BXH is executed, a value of -4 is added to register 10, thus reducing the value in register 10 by 4. The new value in register 10 is compared with the -4 value in register 9. The branch is taken each time until the value in register 10 is -4. Then the branch is not taken, and the SR instruction sets register 8 to zero.

### BRANCH ON INDEX LOW OR EQUAL (BXLE)

The BRANCH ON INDEX LOW OR EQUAL instruction performs the same operation as BRANCH ON INDEX HIGH, except that branching occurs when the sum is lower than or equal to (instead of higher than) the compare value. As the instruction which increments and tests an index value in a program loop, BXLE is useful at the end of the loop and BXH at the beginning. The following assembler-language routines illustrate loops with BXLE.

## BXLE Example 1

Assume that a group of ten 32-bit signed binary integers are stored at consecutive locations, starting at location GROUP. The integers are to be added together, and the sum is to be stored at location SUM.

SR	5,5	Set sum to zero
LA	6, GROUP	Load first address
SR	7,7	Set index to zero
LA	8,4	Load increment 4
LA	9,39	Load compare value
LOOP A	5,0(7,6)	Add integer to sum
	BXLE 7,8,LOOP	Test end of loop
ST	5,SUM	Store sum

The two-instruction loop contains an ADD (A) instruction which adds each integer to the contents of general register 5. The ADD instruction uses the contents of general register 7 as an index value to modify the starting address obtained from register 6. Next, BXLE increments the index value by 4, the increment previously loaded into register 8, and compares it with the compare value in register 9, the odd register of this even-odd pair. The compare value was previously set to 39, which is one less than the number of bytes in the data area; this is also the address, relative to the starting address, of the rightmost byte of the last integer to be added. When the last integer has been added, BXLE increments the index value to the next relative address (40), which is found to be greater than the compare value (39) so that no branching takes place.

## BXLE Example 2

The technique illustrated in Example 1 is restricted to loops containing instructions in the RX instruction format. That format allows both a base register and an index register to be specified (double indexing).

For instructions in other formats, where an index register cannot be specified, the previous technique may be modified by having the address itself serve as the index value in a BXLE instruction and by using as the compare value the address of the last byte rather than its relative address. The base register then provides the address directly at each iteration of the loop, and it is not necessary to specify a second register to hold the index value (single indexing).

In the following example, an AND (NI) instruction in the SI instruction format sets to zero the rightmost bit of each of the same group of integers as in Example

1, thus making all of them even. The  $I_2$  field of the NI instruction contains the byte X'FE', which consists of seven ones and a zero. That byte is ANDed into byte 3, the rightmost byte, of each of the integers in turn.

LA	6, GROUP	Load first address
LA	8,4	Load increment 4
LA	9, GROUP+39	Load compare value
LOOP NI	3(6), X'FE'	AND immediate
	BXLE 6,8,LOOP	Test end of loop

The technique shown in Example 2 does not work, however, on an ESA/370 system when it is in the 31-bit addressing mode and the data is located at the rightmost end of a 31-bit address space. In this case, the compare value would be set to  $2^{31}-1$ , which is the largest possible 32-bit signed binary value. The reason the technique does not work is that the BXLE and BXH instructions treat their operands as 32-bit signed binary integers. When the address in general register 6 reaches the value  $2^{31}-4$ , BXLE increments it to a value that is interpreted as  $-2^{31}$ , rather than  $2^{31}$ , and the comparison remains low, which causes looping to continue indefinitely.

This situation can be avoided by not allowing data areas to extend to the rightmost location in a 31-bit address space or by using other techniques; these may include double indexing when possible, as in Example 1, or starting at the end and stepping downward through the data area with a negative increment.

## COMPARE AND FORM CODEWORD (CFC)

See “Sorting Instructions” on page A-53.

## COMPARE HALFWORD (CH)

The COMPARE HALFWORD instruction compares a 16-bit signed binary integer in storage with the contents of a register. For example, assume that:

Register 4 contains FF FF 80 00 = -32,768<sub>10</sub>.

Register 13 contains 00 01 60 50.

Storage locations 16080-16081 contain 8000 = -32,768<sub>10</sub>.

When the instruction:

## Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
49	4	0	D	030

## Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

---

CH 4,X'30'(0,13)

is executed, the contents of locations 16080-16081 are fetched, expanded to 32 bits (the sign bit is propagated to the left), and compared with the contents of register 4. Because the two numbers are equal, condition code 0 is set.

## COMPARE LOGICAL (CL, CLC, CLI, CLR)

The COMPARE LOGICAL instruction differs from the signed-binary comparison instructions (C, CH, CR) in that all quantities are handled as unsigned binary integers or as unstructured data.

### CLC Example

The COMPARE LOGICAL (CLC) instruction can be used to perform the byte-by-byte comparison of storage fields up to 256 bytes in length. For example, assume that the following two fields of data are in storage:

#### Field 1

1886	1891
D1 D6 C8 D5 E2 D6 D5 6B C1 4B C2 4B	

#### Field 2

1900	190B
D1 D6 C8 D5 E2 D6 D5 6B C1 4B C3 4B	

Also assume:

Register 9 contains 00 00 18 80.

Register 7 contains 00 00 19 00.

Execution of the instruction:

## Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
D5	0B	9	006	7	000

## Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

---

CLC 6(12,9),0(7)

sets condition code 1, indicating that the contents of field 1 are lower in value than the contents of field 2.

Because the collating sequence of the EBCDIC code is determined simply by a logical comparison of the bits in the code, the CLC instruction can be used to collate EBCDIC-coded fields. For example, in EBCDIC, the above two data fields are:

Field 1: JOHNSON,A.B.

Field 2: JOHNSON,A.C.

Condition code 1 indicates that JOHNSON,A.B. should precede JOHNSON,A.C. for the fields to be in alphabetic sequence.

### CLI Example

The COMPARE LOGICAL (CLI) instruction compares a byte from the instruction stream with a byte from storage. For example, assume that:

Register 10 contains 00 00 17 00.

Storage location 1703 contains 7E.

Execution of the instruction:

## Machine Format

Op Code	I <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>
95	AF	A	003

## Assembler Format

Op Code D<sub>1</sub>(B<sub>1</sub>),I<sub>2</sub>

---

CLI 3(10),X'AF'

sets condition code 1, indicating that the first operand (the quantity in main storage) is lower than the second (immediate) operand.

### CLR Example

Assume that:

Register 4 contains 00 00 00 01 = 1.

Register 7 contains FF FF FF FF =  $2^{32}$  - 1.

Execution of the instruction:

Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
15	4	7

Assembler Format

Op Code	R <sub>1</sub> , R <sub>2</sub>
CLR	4,7

sets condition code 1. Condition code 1 indicates that the first operand is lower than the second.

If, instead, the signed-binary comparison instruction COMPARE (CR) had been executed, the contents of register 4 would have been interpreted as +1 and the contents of register 7 as -1. Thus, the first operand would have been higher, so that condition code 2 would have been set.

## COMPARE LOGICAL CHARACTERS UNDER MASK (CLM)

The COMPARE LOGICAL CHARACTERS UNDER MASK (CLM) instruction provides a means of comparing bytes selected from a general register to a contiguous field of bytes in storage. The M<sub>3</sub> field of the CLM instruction is a four-bit mask that selects zero to four bytes from a general register, each mask bit corresponding, left to right, to a register byte. In the comparison, the register bytes corresponding to ones in the mask are treated as a contiguous field. The operation proceeds left to right. For example, assume that:

Storage locations 10200-10202 contain F0 BC 7B.

Register 12 contains 00 01 00 00.

Register 6 contains F0 BC 5C 7B.

Execution of the instruction:

Machine Format

Op Code	R <sub>1</sub>	M <sub>3</sub>	B <sub>2</sub>	D <sub>2</sub>
BD	6	D	C	200

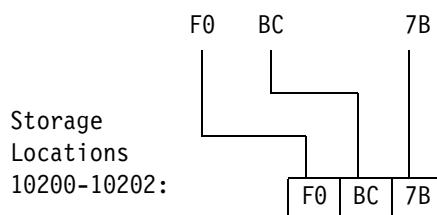

Assembler Format

Op Code R<sub>1</sub>, M<sub>3</sub>, D<sub>2</sub>(B<sub>2</sub>)

CLM 6,B'1101',X'200'(12)

causes the following comparison:

Register 6: F0 BC 5C 7B  
Mask M<sub>3</sub>: 1 1 0 1  
-- -- -- --

Because the selected bytes are equal, condition code 0 is set.

## COMPARE LOGICAL LONG (CLCL)

The COMPARE LOGICAL LONG instruction is used to compare two operands in storage, byte by byte. Each operand can be of any length. Two even-odd pairs of general registers (four registers in all) are used to locate the operands and to control the execution of the CLCL instruction, as illustrated in the following diagram. The first register of each pair must be an even register, and it contains the storage address of an operand. The odd register of each pair contains the length of the operand it covers, and the leftmost byte of the second-operand odd register contains a padding byte which is used to extend the shorter operand, if any, to the same length as the longer operand.

The following illustrates the assignment of registers in the 24-bit addressing mode:

R <sub>1</sub>	/ / / / / /	First-Operand Address
(even)	0	8

R <sub>1</sub> +1	/ / / / / /	First-Operand Length
(odd)	0	8

R <sub>2</sub>		Second-Operand Address	31
(even)	0	8	

R <sub>2+1</sub>	Pad Byte	Second-Operand Length	31
(odd)	0	8	

In the 31-bit addressing mode, the operand addresses would be in bit positions 1-31 of the even registers shown above.

Since the CLCL instruction may be interrupted during execution, the interrupting program must preserve the contents of the four registers for use when the instruction is resumed.

The following instructions set up two register pairs to control a text-string comparison. For example, assume:

#### Operand 1

Address: 20800<sub>16</sub>  
Length: 100<sub>10</sub>

#### Operand 2

Address: 20A00<sub>16</sub>  
Length: 132<sub>10</sub>

#### Padding Byte

Address: 20003<sub>16</sub>  
Length: 1  
Value: 40<sub>16</sub>

Register 12 contains 00 02 00 00.

The setup instructions are:

LA 4,X'800'(12)	Set register 4 to start of first operand
LA 5,100	Set register 5 to length of first operand
LA 8,X'A00'(12)	Set register 8 to start of second operand
LA 9,132	Set register 9 to length of second operand
ICM 9,B'1000',3(12)	Insert padding byte in leftmost byte position of register 9

Register pair 4,5 defines the first operand. Bits 8-31 of register 4 contain the storage address of the start of an EBCDIC text string, and bits 8-31 of register 5 contain the length of the string, in this case 100 bytes.

Register pair 8,9 defines the second operand, with bits 8-31 of register 8 containing the starting location of the second operand and bits 8-31 of register 9 containing the length of the second operand, in this case 132 bytes. Bits 0-7 of register 9 contain an EBCDIC blank character (X'40') to pad the shorter operand. In this example, the padding byte is used in the first operand, after the 100th byte, to compare with the remaining bytes in the second operand.

With the register pairs thus set up, the format of the CLCL instruction is:

#### Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
0F	4	8

#### Assembler Format

Op Code	R <sub>1</sub> ,R <sub>2</sub>
CLCL	4,8

When this instruction is executed, the comparison starts at the left end of each operand and proceeds to the right. The operation ends as soon as an inequality is detected or the end of the longer operand is reached.

If this CLCL instruction is interrupted after 60 bytes have compared equal, the operand lengths in registers 5 and 9 will have been decremented to 40 and 72, respectively. The operand addresses in registers 4 and 8 will have been incremented to X'2083C' and X'20A3C'; the leftmost byte of registers 4 and 8 will have been set to zero. The padding byte X'40' remains in register 9. When the CLCL instruction is reexecuted with these register contents, the comparison resumes at the point of interruption.

Now, assume that the instruction is interrupted after 110 bytes. That is, the first 100 bytes of the second operand have compared equal to the first operand, and the next 10 bytes of the second operand have compared equal to the padding byte (blank). The residual operand lengths in registers 5 and 9 are 0 and 22, respectively, and the operand addresses in registers 4 and 8 are X'20864' (the value when the first operand was exhausted) and X'20A6E' (the current value for the second operand).

When the comparison ends, the condition code is set to 0, 1, or 2, depending on whether the first operand

is equal to, less than, or greater than the second operand, respectively.

When the operands are unequal, the addresses in registers 4 and 8 indicate the bytes that caused the mismatch.

## COMPARE LOGICAL STRING (CLST)

The COMPARE LOGICAL STRING instruction is used to compare a first operand designated by general register R<sub>1</sub> and a second operand designated by general register R<sub>2</sub>. The comparison is made left to right, byte by byte, until unequal bytes are compared, an ending character specified in general register 0 is encountered in either operand, or a CPU-determined number of bytes have been compared. The condition code is set to 0 if the two operands are equal, to 1 if the first operand is low, to 2 if the second operand is low, or to 3 if a CPU-determined number of bytes have been compared. If the ending character is found in both operands simultaneously, the operands are equal. If it is found in only one operand, that operand is low.

When condition code 1 or 2 is set, the addresses of the last bytes processed in the first and second operands are placed in general registers R<sub>1</sub> and R<sub>2</sub>, respectively. These are the addresses of unequal bytes in the two operands, or they are the address of an ending character in one operand and of the byte in the corresponding byte position in the other operand. When condition code 3 is set, the addresses of the next bytes to be processed are placed in the registers. When condition code 0 is set, the contents of the registers remain unchanged.

Following are examples of first and second operands beginning at decimal locations 1000 and 2000, respectively. The addresses in general registers R<sub>1</sub> and R<sub>2</sub> are 1000 and 2000, respectively. The ending character in general register 0 is 00 hex (as in the C programming language). The values of the operand bytes are shown in hex, and the resulting condition code and final contents of general registers R<sub>1</sub> and R<sub>2</sub> are shown.

### Example 1

1000            2000  
C1 C2 C3 00    C1 C2 C3 00  
  
CC: 0; (R<sub>1</sub>): 1000; (R<sub>2</sub>): 2000

### Example 2

1000            2000  
40 40 40 C1    40 40 40 C2  
  
CC: 1; (R<sub>1</sub>): 1003; (R<sub>2</sub>): 2003

### Example 3

1000            2000  
40 40 40 C2    40 40 40 C1  
  
CC: 2; (R<sub>1</sub>): 1003; (R<sub>2</sub>): 2003

### Example 4

1000            2000  
C1 C2 C3 00    C1 C2 C3 C4  
  
CC: 1; (R<sub>1</sub>): 1003; (R<sub>2</sub>): 2003

### Example 5

1000            2000  
C1 C2 C3 C4    C1 C2 C3 00  
  
CC: 2; (R<sub>1</sub>): 1003; (R<sub>2</sub>): 2003

### Example 6

Assuming that the CPU-determined number of bytes compared is 256:

1000        1256    2000        2256  
40 .. 40 00    40 .. 40 00  
  
CC: 3; (R<sub>1</sub>): 1256; (R<sub>2</sub>): 2256

### Example 7

1000            2000  
00 40 40 40    40 40 40 40  
  
CC: 1; (R<sub>1</sub>): 1000; (R<sub>2</sub>): 2000

### Example 8

1000            2000  
40 40 40 40    00 40 40 40  
  
CC: 2; (R<sub>1</sub>): 1000; (R<sub>2</sub>): 2000

### Example 9

1000            2000  
00 40 40 40    00 40 40 40  
  
CC: 0; (R<sub>1</sub>): 1000; (R<sub>2</sub>): 2000

## CONVERT TO BINARY (CVB)

The CONVERT TO BINARY instruction converts an eight-byte, signed-packed-decimal number into a signed binary integer and loads the result into a gen-

eral register. After the conversion operation is completed, the number is in the proper form for use as an operand in signed binary arithmetic. For example, assume:

Storage locations 7608-760F contain a decimal number in the signed-packed-decimal format: 00 00 00 00 25 59 4C (+25,594).

The contents of register 7 are not significant.

Register 13 contains 00 00 76 00.

The format of the conversion instruction is:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
4F	7	0	D	008

Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

CVB 7,8(0,13)

After the instruction is executed, register 7 contains 00 00 63 FA.

## CONVERT TO DECIMAL (CVD)

The CONVERT TO DECIMAL instruction is the opposite of the CONVERT TO BINARY instruction. CVD converts a signed binary integer in a register to signed-packed-decimal number and stores the eight-byte result. For example, assume:

Register 1 contains the signed binary integer: 00 00 0F 0F.

Register 13 contains 00 00 76 00.

The format of the instruction is:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
4E	1	0	D	008

Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

CVD 1,8(0,13)

After the instruction is executed, storage locations 7608-760F contain 00 00 00 00 00 03 85 5C (+3855).

The plus sign generated is the preferred plus sign, 1100<sub>2</sub>.

## DIVIDE (D, DR)

The DIVIDE instruction divides the dividend in an even-odd register pair by the divisor in a register or in storage. Since the instruction assumes the dividend to be 64 bits long, it is important first to extend a 32-bit dividend on the left with bits equal to the sign bit. For example, assume that:

Storage locations 3550-3553 contain 00 00 08 DE = 2270<sub>10</sub> (the dividend).

Storage locations 3554-3557 contain 00 00 00 32 = 50<sub>10</sub> (the divisor).

The initial contents of registers 6 and 7 are not significant.

Register 8 contains 00 00 35 50.

The following assembler-language statements load the registers properly and perform the divide operation:

Statement	Comments
L 6,0(0,8)	Places 00 00 08 DE into register 6.
SRDA 6,32(0)	Shifts 00 00 08 DE into register 7.
	Register 6 is filled with zeros (sign bits).
D 6,4(0,8)	Performs the division.

The machine format of the above DIVIDE instruction is:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
5D	6	0	8	004

After the instructions listed above are executed:

Register 6 contains 00 00 00 14 = 20<sub>10</sub> = the remainder.

Register 7 contains 00 00 00 2D = 45<sub>10</sub> = the quotient.

Note that if the dividend had not been first placed in register 6 and shifted into register 7, register 6 might not have been filled with the proper dividend-sign bits (zeros in this example), and the DIVIDE instruction might not have given the expected results.

## EXCLUSIVE OR (X, XC, XI, XR)

When the Boolean operator EXCLUSIVE OR is applied to two bits, the result is one when either, but not both, of the two bits is one; otherwise, the result is zero. When two bytes are EXCLUSIVE ORed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of the EXCLUSIVE OR of two bytes:

First-operand byte: 0011 0101<sub>2</sub>  
Second-operand byte: 0101 1100<sub>2</sub>

Result byte: 0110 1001<sub>2</sub>

### XC Example

The EXCLUSIVE OR (XC) instruction can be used to exchange the contents of two areas in storage without the use of an intermediate storage area. For example, assume two three-byte fields in storage:

Field 1      359      35B  
       00 | 17 | 90

Field 2      360      362  
       00 | 14 | 01

Execution of the instruction (assume that register 7 contains 00 00 03 58):

#### Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
D7	02	7	001	7	008

#### Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

XC 1(3,7),8(7)

Field 1 is EXCLUSIVE ORed with field 2 as follows:

Field 1: 00000000 00010111 10010000<sub>2</sub> = 00 17 90<sub>16</sub>  
Field 2: 00000000 00010100 00000001<sub>2</sub> = 00 14 01<sub>16</sub>

Result: 00000000 00000011 10010001<sub>2</sub> = 00 03 91<sub>16</sub>

The result replaces the former contents of field 1. Condition code 1 is set to indicate a nonzero result.

Now, execution of the instruction:

#### Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
D7	02	7	008	7	001

#### Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

XC 8(3,7),1(7)

produces the following result:

Field 1: 00000000 00000011 10010001<sub>2</sub> = 00 03 91<sub>16</sub>  
Field 2: 00000000 00010100 00000001<sub>2</sub> = 00 14 01<sub>16</sub>

Result: 00000000 00010111 10010000<sub>2</sub> = 00 17 90<sub>16</sub>

The result of this operation replaces the former contents of field 2. Field 2 now contains the original value of field 1. Condition code 1 is set to indicate a nonzero result.

Lastly, execution of the instruction:

#### Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
D7	02	7	001	7	008

#### Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

XC 1(3,7),8(7)

produces the following result:

Field 1: 00000000 00000011 10010001<sub>2</sub> = 00 03 91<sub>16</sub>  
Field 2: 00000000 00010111 10010000<sub>2</sub> = 00 17 90<sub>16</sub>

Result: 00000000 00010100 00000001<sub>2</sub> = 00 14 01<sub>16</sub>

The result of this operation replaces the former contents of field 1. Field 1 now contains the original value of field 2. Condition code 1 is set to indicate a nonzero result.

## XI Example

A frequent use of the EXCLUSIVE OR (XI) instruction is to invert a bit (change a zero bit to a one or a one bit to a zero). For example, assume that storage location 8082 contains 0110 1001<sub>2</sub>. To invert the leftmost and rightmost bits without affecting any of the other bits, the following instruction can be used (assume that register 9 contains 00 00 80 80):

### Machine Format

Op Code	I <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>
97	81	9	002

### Assembler Format

Op Code D<sub>1</sub>(B<sub>1</sub>) , I<sub>2</sub>

---

XI 2(9),X'81'

When the instruction is executed, the byte in storage is EXCLUSIVE ORed with the immediate byte (the I<sub>2</sub> field of the instruction):

Location 8082: 0110 1001<sub>2</sub>  
Immediate byte: 1000 0001<sub>2</sub>

---

Result: 1110 1000<sub>2</sub>

The resulting byte is stored back in location 8082. Condition code 1 is set to indicate a nonzero result.

### Notes:

- With the XC instruction, fields up to 256 bytes in length can be exchanged.
- With the XR instruction, the contents of two registers can be exchanged.
- Because the X instruction operates storage to register only, an exchange cannot be made solely by the use of X.
- A field EXCLUSIVE ORed with itself is cleared to zeros.
- For additional examples of the use of EXCLUSIVE OR, see "Hexadecimal-Floating-Point-Number Conversion" on page A-44.

## EXECUTE (EX)

The EXECUTE instruction causes one *target instruction* in main storage to be executed out of sequence

without actually branching to the target instruction. Unless the R<sub>1</sub> field of the EXECUTE instruction is zero, bits 8-15 of the target instruction are ORed with bits 56-63 of the R<sub>1</sub> register before the target instruction is executed. Thus, EXECUTE may be used to supply the length field for an SS instruction without modifying the SS instruction in storage. For example, assume that a MOVE (MVC) instruction is the target that is located at address 3820, with a format as follows:

### Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
D2	00	C	003	D	000

### Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>) , D<sub>2</sub>(B<sub>2</sub>)

---

MVC 3(1,12),0(13)

where register 12 contains 00 00 89 13 and register 13 contains 00 00 90 A0.

Further assume that at storage address 5000, the following EXECUTE instruction is located:

### Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
44	1	0	A	000

### Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

---

EX 1,0(0,10)

where register 10 contains 00 00 38 20 and register 1 contains 00 0F F0 03.

When the instruction at 5000 is executed, the rightmost byte of register 1 is ORed with the second byte of the target instruction:

Instruction byte: 0000 0000<sub>2</sub> = 00  
Register byte: 0000 0011<sub>2</sub> = 03

---

Result: 0000 0011<sub>2</sub> = 03

causing the instruction at 3820 to be executed as if it originally were:

## Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
D2	03	C	003	D	000

## Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

---

MVC 3(4,12),0(13)

However, after execution:

Register 1 is unchanged.

The instruction at 3820 is unchanged.

The contents of the four bytes starting at location 90A0 have been moved to the four bytes starting at location 8916.

The CPU next executes the instruction at address 5004 (PSW bits 104-127 contain 00 50 04).

## FIND LEFTMOST ONE (FLOGR)

FIND LEFTMOST ONE may be used to locate free objects, the availability of which is tracked in a hierarchical bit map.

In the following example, the hierarchical bit map consists of multiple levels of bits, each level having 64 times the number of bits as the next lower-numbered level. This example shows four levels, mapping a total of 16M objects, however additional levels may be added to manage larger numbers of objects.

The highest-numbered bit map level (L3 in this illustration) represents the availability of individual objects, for example, records or pages. A one bit indicates that the object is available, and a zero bit means that the object is not available.

In lower-numbered bit map levels (L0, L1, and L2 in this illustration), a bit position corresponds to a doubleword in the next higher-numbered level. When a bit in a lower-numbered bit map level is one, at least one bit of the corresponding doubleword in the higher-level is one. When a bit in a lower-number bit

map level is zero, no bits in the corresponding higher-level doubleword are one.

An example of using FIND LEFTMOST ONES to quickly locate the next available lowest-numbered object, as mapped by such a hierarchical bit map, is shown below. Upon completion, at the label "FOUND", general register 15 contains the number of the located object. If no objects are available, the code branches to the label "NOTFND".

LA	15,0	Zero accumulator
LA	9,OFFSET	Point to table
LA	10,4	Load increment
LA	11,ENDOFF-1	Load compare value
FIND	LGR 7,15	Copy accum. to R7
	ALGF 7,0(,9)	Add # DWs to bits
	SLLG 7,7,3	Get byte offset
	LG 1,BITS(7)	Get DW to test
	FLOGR 0,1	Find leftmost one
	BZ NOTFND	No one bits found
	SLLG 15,15,6	Times # bits in DW
	AGR 15,0	Add bit just found
	BXLEG 9,10,FIND	Do for each level
FOUND	STG 1,BITS(7)	Update changed bit
	...	
	NOTFND [Any instruction]	
OFFSET	DC A((L0-BITS)/8)	Offset to level 0
	DC A((L1-BITS)/8)	Offset to level 1
	DC A((L2-BITS)/8)	Offset to level 2
	DC A((L3-BITS)/8)	Offset to level 3
ENDOFF	EQU *	End of table
BITS	DS 0D	Start of bit map
L0	DS FD	-L0 (64 objects)
L1	DS 64FD	-L1 (4K objects)
L2	DS (64*64)FD	-L2 (256K objects)
L3	DS (64*64*64)FD	-L3 (16M objects)

This code sequence shows the zeroing of the found bit with the STORE (STG) instruction at the label "FOUND". Proper maintenance of such a hierarchical bit map requires that when all bits of a doubleword become zeros, the corresponding bit in the next lower-numbered level is set to zeros. Similarly, when adding a free object to the highest level, the corresponding bits in lower-numbered levels must be set to one. These maintenance functions are not shown.

Note, in a multiprocessing environment, access to the bit map is assumed to be serialized for the duration of the update process.

## INSERT CHARACTERS UNDER MASK (ICM)

The INSERT CHARACTERS UNDER MASK (ICM) instruction may be used to replace all or selected bytes in a general register with bytes from storage and to set the condition code to indicate the value of the inserted field.

For example, if it is desired to insert a three-byte address from FIELDA into register 5 and leave the leftmost byte of the register unchanged, assume:

Machine Format

Op Code	R <sub>1</sub>	M <sub>3</sub>	S <sub>2</sub>
BF	5	7	* * * *

Assembler Format

Op Code R<sub>1</sub>,M<sub>3</sub>,S<sub>2</sub>

---

ICM 5,B'0111',FIELD A

FIELDA:	FE DC BA
Register 5 (before):	12 34 56 78
Register 5 (after):	12 FE DC BA
Condition code (after):	1 (leftmost bit of inserted field is one)

As another example:

Machine Format

Op Code	R <sub>1</sub>	M <sub>3</sub>	S <sub>2</sub>
BF	6	9	* * * *

Assembler Format

Op Code R<sub>1</sub>,M<sub>3</sub>,S<sub>2</sub>

---

ICM 6,B'1001',FIELD B

FIELDB:	12 34
Register 6 (before):	00 00 00 00
Register 6 (after):	12 00 00 34
Condition code (after):	2 (inserted field is nonzero with leftmost zero bit)

When the mask field contains 1111, the ICM instruction produces the same result as LOAD (L) (provided that the indexing capability of the RX format is not

needed), except that ICM also sets the condition code. The condition-code setting is useful when an all-zero field (condition code 0) or a leftmost one bit (condition code 1) is used as a flag.

## LOAD (L, LR)

The LOAD instruction takes four bytes from storage or from a general register and place them unchanged into a general register. For example, assume that the four bytes starting with location 21003 are to be loaded into register 10. Initially:

Register 5 contains 00 02 00 00.

Register 6 contains 00 00 10 03.

The contents of register 10 are not significant.

Storage locations 21003-21006 contain 00 00 AB CD.

To load register 10, the RX form of the instruction can be used:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
58	A	5	6	000

Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

---

L 10,0(5,6)

After the instruction is executed, register 10 contains 00 00 AB CD.

## LOAD ADDRESS (LA)

The LOAD ADDRESS instruction provides a convenient way to place a nonnegative binary integer up to  $4095_{10}$  in a register without first defining a constant and then using it as an operand. For example, the following instruction places the number  $2048_{10}$  in register 1:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
41	1	0	0	800

Assembler Format  
Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

---

LA 1,2048(0,0)

The LOAD ADDRESS instruction can also be used to increment a register by an amount up to 4095<sub>10</sub> specified in the D<sub>2</sub> field. Depending on the addressing mode, only the rightmost 24 or 31 bits of the sum are retained, however. The leftmost bits of the 32-bit result are set to zeros. For example, assume that register 5 contains 00 12 34 56.

The instruction:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
41	5	0	5	00A

Assembler Format  
Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

---

LA 5,10(0,5)

adds 10 (decimal) to the contents of register 5 as follows:

Register 5 (old): 00 12 34 56  
D<sub>2</sub> field: 00 00 00 0A

---

Register 5 (new): 00 12 34 60

The register may be specified as either B<sub>2</sub> or X<sub>2</sub>. Thus, the instruction LA 5,10(5,0) produces the same result.

As the most general example, the instruction LA 6,10(5,4) forms the sum of three values: the contents of register 4, the contents of register 5, and a displacement of 10 and places the 24-bit or 31-bit sum with zeros appended on the left in register 6.

## LOAD HALFWORD (LH)

The LOAD HALFWORD instruction places unchanged a halfword from storage into the right half of a register. The left half of the register is loaded with zeros or ones according to the sign (leftmost bit) of the halfword.

For example, assume that the two bytes in storage locations 1803-1804 are to be loaded into register 6. Also assume:

The contents of register 6 are not significant.

Register 14 contains 00 00 18 03.

Locations 1803-1804 contain 00 20.

The instruction required to load the register is:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
48	6	0	E	000

Assembler Format  
Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

---

LH 6,0(0,14)

After the instruction is executed, register 6 contains 00 00 00 20. If locations 1803-1804 had contained a negative number, for example, A7 B6, a minus sign would have been propagated to the left, giving FF FF A7 B6 as the final result in register 6.

## MOVE (MVC, MVI)

### MVC Example

The MOVE (MVC) instruction can be used to move data from one storage location to another. For example, assume that the following two fields are in storage:

Field 2048	C1	C2	C3	C4	C5	C6	C7	C8	C9	CA	CB	2052
1												
Field 3840	F1	F2	F3	F4	F5	F6	F7	F8	F9			3848
2												

Also assume:

Register 1 contains 00 00 20 48.

Register 2 contains 00 00 38 40.

With the following instruction, the first eight bytes of field 2 replace the first eight bytes of field 1:

## Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
D2	07	1	000	2	000

## Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

---

MVC 0(8,1),0(2)

After the instruction is executed, field 1 becomes:

Field	2048	2052
1	F1 F2 F3 F4 F5 F6 F7 F8	C9 CA CB

Field 2 is unchanged.

MVC can also be used to propagate a byte through a field by starting the first-operand field one byte location to the right of the second-operand field. For example, suppose that an area in storage starting with address 358 contains the following data:

358	360
00 F1 F2 F3 F4 F5 F6 F7 F8	

With the following MVC instruction, the zeros in location 358 can be propagated throughout the entire field (assume that register 11 contains 00 00 03 58):

## Machine Format

Op Code L B<sub>1</sub> D<sub>1</sub> B<sub>2</sub> D<sub>2</sub>  
D2 07 B 001 B 000

## Assembler Format

---

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

MVC 1(8,11),0(11)

Because MVC is executed as if one byte were processed at a time, the above instruction, in effect, takes the byte at address 358 and stores it at 359 (359 now contains 00), takes the byte at 359 and stores it at 35A, and so on, until the entire field is filled with zeros. Note that an MVI instruction could have been used originally to place the byte of zeros in location 358.

## Notes:

1. Although the field occupying locations 358-360 contains nine bytes, the length coded in the assembler format is equal to the number of moves (one less than the field length).

2. The order of operands is important even though only one field is involved.

## MVI Example

The MOVE (MVI) instruction places one byte of information from the instruction stream into storage. For example, the instruction:

## Machine Format

Op Code	I <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>
92	5B	1	000

## Assembler Format

---

Op Code D<sub>1</sub>(B<sub>1</sub>),I<sub>2</sub>

MVI 0(1),C'\$'

may be used, in conjunction with the instruction EDIT AND MARK, to insert the EBCDIC code for a dollar symbol at the storage address contained in general register 1 (see also the example for EDIT AND MARK).

## MOVE INVERSE (MVCIN)

The MOVE INVERSE (MVCIN) instruction can be used to move data from one storage location to another while reversing the order of the bytes within the field. For example, assume that the following two fields are in storage:

Field	2048	2052
1	C1 C2 C3 C4 C5 C6 C7 C8	C9 CA CB

Field	3840	3848
2	F1 F2 F3 F4 F5 F6 F7 F8	F9

Also assume:

Register 1 contains 00 00 20 48.

Register 2 contains 00 00 38 40.

With the following instruction, the first eight bytes of field 2 replace the first eight bytes of field 1:

### Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
E8	07	1	000	2	007

### Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

MVCIN 0(8,1),7(2)

After the instruction is executed, field 1 becomes:

Field	2048	2052
1	F8 F7 F6 F5 F4 F3 F2 F1 C9 CA CB	

2048                    2052

Field 2 is unchanged.

**Note:** This example uses the same general registers, storage locations, and original values as the first example for MVC. For MVCIN, the second-operand address must designate the rightmost byte of the field to be moved, in this case location 3847. This is accomplished by means of the 7 in the D<sub>2</sub> field of the instruction.

## MOVE LONG (MVCL)

The MOVE LONG (MVCL) instruction can be used for moving data in storage as in the first example of the MVC instruction, provided that the two operands do not overlap. MVCL differs from MVC in that the address and length of each operand are specified in an even-odd pair of general registers. Consequently, MVCL can be used to move more than 256 bytes of data with one instruction. As an example, assume:

- Register 2 contains 00 0A 00 00.
- Register 3 contains 00 00 08 00.
- Register 8 contains 00 06 00 00.
- Register 9 contains 00 00 08 00.

Execution of the instruction:

### Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
0E	8	2

### Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

MVCL 8,2

moves 2,048<sub>10</sub> bytes from locations A0000-A07FF to locations 60000-607FF. Assuming that the CPU is in the 24-bit addressing mode, bits 8-31 of registers 2 and 8 are incremented by 800<sub>16</sub>, and bits 0-7 of registers 2 and 8 are set to zeros. Bits 8-31 of registers 3 and 9 are decremented to zero. Condition code 0 is set to indicate that the operand lengths are equal.

If register 3 had contained F0 00 04 00, only the 1,024<sub>10</sub> bytes from locations A0000-A03FF would have been moved to locations 60000-603FF. The remaining locations 60400-607FF of the first operand would have been filled with 1,024 copies of the padding byte X'F0', as specified by the leftmost byte of register 3. Bits 8-31 of register 2 would have been incremented by 400<sub>16</sub>, bits 8-31 of register 8 would have been incremented by 800<sub>16</sub>, and bits 0-7 of registers 2 and 8 would have been set to zeros. Bits 8-31 of registers 3 and 9 would still have been decremented to zero. Condition code 2 would have been set to indicate that the first operand was longer than the second.

The technique for setting a field to zeros that is illustrated in the second example of MVC cannot be used with MVCL. If the registers were set up to attempt such an operation with MVCL, no data movement would take place and condition code 3 would indicate destructive overlap.

Instead, MVCL may be used to clear a storage area to zeros as follows. Assume register 8 and 9 are set up as before. Register 3 contains only zeros, specifying zero length for the second operand and a zero padding byte. Register 2 is not used to access storage, and its contents are not significant. Executing the instruction MVCL 8,2 causes locations 60000-607FF to be filled with zeros. Bits 8-31 of register 8 are incremented by 800<sub>16</sub>, and bits 0-7 of registers 2 and 8 are set to zeros. Bits 8-31 of register 9 are decremented to zero, and condition code 2 is set to indicate that the first operand is longer than the second.

## MOVE NUMERICS (MVN)

Two related instructions, MOVE NUMERICS and MOVE ZONES, may be used with decimal data in the zoned format to operate separately on the rightmost

four bits (the numeric bits) and the leftmost four bits (the zone bits) of each byte. Both are similar to MOVE (MVC), except that MOVE NUMERICS moves only the numeric bits and MOVE ZONES moves only the zone bits.

To illustrate the operation of the MOVE NUMERICS instruction, assume that the following two fields are in storage:

Field	7090	7093
A	C6 C7	C8 C9

Field	7041	7046
B	F0 F1	F2 F3 F4 F5

Also assume:

Register 14 contains 00 00 70 90.

Register 15 contains 00 00 70 40.

After the instruction:

Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
D1	03	F	001	E	000

Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

---

MVN 1(4,15),0(14)

is executed, field B becomes:

7041	7046
F6 F7 F8 F9	F4 F5

The numeric bits of the bytes at locations 7090-7093 have been stored in the numeric bits of the bytes at locations 7041-7044. The contents of locations 7090-7093 and 7045-7046 are unchanged.

## MOVE STRING (MVST)

The MOVE STRING instruction is used to move a second operand designated by general register R<sub>2</sub> to a first-operand location designated by general register R<sub>1</sub>. The movement is made left to right until an ending character specified in general register 0 has been moved or a CPU-determined number of bytes

have been moved. The condition code is set to 1 if the ending character was moved or to 3 if a CPU-determined number of bytes were moved.

When condition code 1 is set, the address of the ending character in the first operand is placed in general register R<sub>1</sub>, and the contents of general register R<sub>2</sub> remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the first and second operands is placed in general registers R<sub>1</sub> and R<sub>2</sub>, respectively.

Following is an example program that sets string A equal to the concatenation of string B followed by string C, where the length of each of strings B and C is unknown, and the end of each of strings B and C is indicated by an ending character of 00 hex (as in the C programming language). The program is not written for execution in the access-register mode.

L	4, STRAADR
L	5, STRBADR
SR	0,0
LOOP1	MVST 4,5
	BC 1, LOOP1
	L 5, STRCADR
LOOP2	MVST 4,5
	BC 1, LOOP2
	[Any instruction]

## MOVE WITH OFFSET (MVO)

MOVE WITH OFFSET may be used to shift a signed-packed-decimal number an odd number of digit positions or to concatenate a sign to an unsigned-packed-decimal number.

Assume that the three-byte unsigned-packed-decimal number in storage locations 4500-4502 is to be moved to locations 5600-5603 and given the sign of the signed-packed-decimal number ending at location 5603. Also assume:

Register 12 contains 00 00 56 00.

Register 15 contains 00 00 45 00.

Storage locations 5600-5603 contain 77 88 99 0C.

Storage locations 4500-4502 contain 12 34 56.

After the instruction:

## Machine Format

Op Code	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
F1	3	2	C	000	F	000

## Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

MV0 0(4,12),0(3,15)

is executed, the storage locations 5600-5603 contain 01 23 45 6C. Note that the second operand is extended on the left with one zero to fill out the first-operand field.

## MOVE ZONES (MVZ)

The MOVE ZONES instruction can operate on overlapping or nonoverlapping fields, as can the instructions MOVE (MVC) and MOVE NUMERICS. When operating on nonoverlapping fields, MOVE ZONES works like the MOVE NUMERICS instruction (see its example), except that MOVE ZONES moves only the zone bits of each byte. To illustrate the use of MOVE ZONES with overlapping fields, assume that the following data field is in storage:

800	805
F1 C2 F3 C4 F5 C6	

Also assume that register 15 contains 00 00 08 00. The instruction:

## Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
D3	04	F	001	F	000

## Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

MVZ 1(5,15),0(15)

propagates the zone bits from the byte at address 800 through the entire field, so that the field becomes:

800	805
F1 F2 F3 F4 F5 F6	

## MULTIPLY (M, MR)

Assume that a number in register 5 is to be multiplied by the contents of a four-byte field at address 3750. Initially:

The contents of register 4 are not significant.

Register 5 contains 00 00 00 9A = 154<sub>10</sub> = the multiplicand.

Register 11 contains 00 00 06 00.

Register 12 contains 00 00 30 00.

Storage locations 3750-3753 contain 00 00 00 83 = 131<sub>10</sub> = the multiplier.

The instruction required for performing the multiplication is:

## Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
5C	4	B	C	150

## Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

M 4,X'150'(11,12)

After the instruction is executed, the product is in the register pair 4 and 5:

Register 4 contains 00 00 00 00.

Register 5 contains 00 00 4E CE = 20,174<sub>10</sub>.

Storage locations 3750-3753 are unchanged.

The RR format of the instruction can be used to square the number in a register. Assume that register 7 contains 00 01 00 05. The contents of register 6 are not significant. The instruction:

## Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
1C	6	7

## Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

MR 6,7

multiplies the number in register 7 by itself and places the result in the pair of registers 6 and 7:

Register 6 contains 00 00 00 01.

Register 7 contains 00 0A 00 19.

## MULTIPLY HALFWORD (MH)

The MULTIPLY HALFWORD instruction is used to multiply the contents of a register by a two-byte field in storage. For example, assume that:

Register 11 contains 00 00 00 15 =  $21_{10}$  = the multiplicand.

Register 14 contains 00 00 01 00.

Register 15 contains 00 00 20 00.

Storage locations 2102-2103 contain FF D9 = -  $39_{10}$  = the multiplier.

The instruction:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
4C	B	E	F	002

Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

MH 11,2(14,15)

multiplies the two numbers. The product, FF FF FC CD = - $819_{10}$ , replaces the original contents of register 11.

Only the rightmost 32 bits of a product are stored in a register; any significant bits on the left are lost. No program interruption occurs on overflow.

## OR (O, OC, OI, OR)

When the Boolean operator OR is applied to two bits, the result is one when either bit is one; otherwise, the result is zero. When two bytes are ORed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of ORing two bytes:

First-operand byte: 0011 0101<sub>2</sub>

Second-operand byte: 0101 1100<sub>2</sub>

Result byte: 0111 1101<sub>2</sub>

## OI Example

A frequent use of the OR instruction is to set a particular bit to one. For example, assume that storage location 4891 contains 0100 0010<sub>2</sub>. To set the rightmost bit of this byte to one without affecting the other bits, the following instruction can be used (assume that register 8 contains 00 00 48 90):

Machine Format

Op Code	I <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>
96	01	8	001

Assembler Format

Op Code D<sub>1</sub>(B<sub>1</sub>), I<sub>2</sub>

OI 1(8), X'01'

When this instruction is executed, the byte in storage is ORed with the immediate byte (the I<sub>2</sub> field of the instruction):

Location 4891: 0100 0010<sub>2</sub>  
Immediate byte: 0000 0001<sub>2</sub>

Result: 0100 0011<sub>2</sub>

The resulting byte with bit 7 set to one is stored back in location 4891. Condition code 1 is set.

## PACK (PACK)

Assume that storage locations 1000-1003 contain the following zoned-decimal number that is to be converted to a signed-packed-decimal number and left in the same location:

Zoned number		1000	1003
F1	F2	F3	C4

Also assume that register 12 contains 00 00 10 00. After the instruction:

Machine Format

Op Code	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
F2	3	3	C	000	C	000

Assembler Format  
Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

PACK 0(4,12),0(4,12)

is executed, the result in locations 1000-1003 is in the signed-packed-decimal format:

Signed-packed number      

1000	1003		
00	01	23	4C

#### Notes:

1. This example illustrates the operation of PACK when the first- and second-operand fields overlap completely.
2. During the operation, the second operand was extended on the left with zeros.

## ROTATE THEN EXCLUSIVE OR SELECTED BITS

The following example illustrates the use of ROTATE THEN EXCLUSIVE OR SELECTED BITS to determine if the access-control bits of a page's storage-protection key match the key in the PSW. In this example, only the condition code is set; the result is not placed in the first-operand register.

```
LAY 9,BLOCK Point to storage block.  
IVSK 14,9 Insert key into bits 56-63.  
EPSW 4,0 Extract PSW key (bits 40-43).  
RXSBG 4,14,128+40,43,16 Compare keys.
```

On completion, the condition code will be set to zero if the PSW key matches the access-control bits in the storage key of page addressed by general register 9. Condition code 1 will be set if the keys do not match.

## ROTATE THEN INSERT SELECTED BITS

1. The following example illustrates the use of ROTATE THEN INSERT SELECTED BITS to extract the various DAT-table indices of a virtual address contained in general register 8. This example shows the use of the zero-remaining-bits control to set the remaining bits of the result registers to zero.

The virtual address in general register 8 is assumed to be 123456789ABCDEF0 hex.

```
RISBG 1,8,53,128+63,11 Get reg. 1st index.  
RISBG 2,8,53,128+63,22 Get reg. 2nd index.  
RISBG 3,8,53,128+63,33 Get reg. 3rd index.  
RISBG 4,8,53,128+63,44 Get segment index.  
RISBG 5,8,56,128+63,52 Get page index.  
RISBG 6,8,52,128+63,0 Get byte index.
```

The condition code following each RISBG is 2. On completion, general registers 1-6 contain the region-first index, region-second index, region-third index, segment index, page index, and byte index, respectively, as follows:

```
GR1: 0000000000000001 (RFX)  
GR2: 0000000000000015 (RSX)  
GR3: 00000000000004F1 (RTX)  
GR4: 000000000000001AB (SX)  
GR5: 000000000000000CD (PX)  
GR6: 0000000000000EF0 (BX)
```

2. The following example illustrates shifting a 64-bit value to the left by *L* bits:

RISBG R<sub>1</sub>,R<sub>2</sub>,0,X'80'+63-*L*,*L*

3. The following example illustrates shifting a 32-bit value to the right by *R* bits and setting the left-most 32 bits to zero:

RISBG R<sub>1</sub>,R<sub>2</sub>,32+*R*,X'80'+63,-*R*

4. The following example illustrates zeroing bits *S* through *E* of general register 3.

RISBG 3,3,mod64(*E*+1),128+mod64(*S*-1),0

Mod64 represents a modulo function which effectively ANDs the value in parentheses with 3F hex.

## ROTATE THEN OR SELECTED BITS

The following example illustrates the use of ROTATE THEN OR SELECTED BITS to rotate and combine selected bits of general registers 6 and 8.

```
LG 6,=X'004C487040CF4600'  
LG 8,=X'C07FAF37FC968280'  
ROSBG 6,8,8,54,32
```

On completion, condition code 1 is set, and general register 6 is as follows:

GR6: 00DECAF0C0FFEE00

Note that only bits 8-54 of the registers are ORed; bits 0-7 and 55-63 of general register 6 are not modified.

## SEARCH STRING (SRST)

The SEARCH STRING instruction is used to search a second operand designated by general register R<sub>2</sub> for a character specified in general register 0. The length of the second operand is known — the address of the first byte after the second operand is in general register R<sub>1</sub>.

When the specified character is found, condition code 1 is set, the address of the character is placed in general register R<sub>1</sub>, and the contents of general register R<sub>2</sub> remain unchanged. When the address of the next second-operand byte to be examined equals the address in general register R<sub>1</sub>, condition code 2 is set, and the contents of general register R<sub>1</sub> and R<sub>2</sub> remain unchanged. When a CPU-determined number of second-operand bytes have been examined, condition code 3 is set, the address of the next byte to be processed in the second operand is placed in general register R<sub>2</sub>, and the contents of general register R<sub>1</sub> remain unchanged.

### SRST Example 1

Following is an example program that determines the end of string A, as indicated by an ending character equal to 00 hex (as in the C programming language), and then determines the address of the first character equal to C1 hex in the string. The program is based on the assumption that the second operand does not begin at location 0 or wrap around in storage, and, therefore, condition code 2 will not be set by the first SEARCH STRING instruction because of the address in general register 0. The program is not written for execution in the access-register mode.

```
L      5,STRAADR
SR    0,0
L0OP1 SRST 0,5
BC    1,L0OP1
L      5,STRAADR
LR    4,0
LA    0,X'C1'
```

```
LOOP2 SRST 4,5
BC    1,LOOP2
BC    2,NOTFND
FOUND [Any instruction]
...
NOTFND [Any instruction]
```

### SRST Example 2

Following is an example program that determines the address of the first character equal to C1 hex in the string A whose length is known. The program is not written for execution in the access-register mode.

```
L      5,STRAADR
L      4,STRALEN
AR    4,5
LA    0,X'C1'
L0OP1 SRST 4,5
BC    1,L0OP1
BC    2,NOTFND
FOUND [Any instruction]
...
NOTFND [Any instruction]
```

In this example, the value in STRALEN may be a length that either does or does not include an ending character at the end of the string, provided that the ending character is not the character for which the search is made.

## SHIFT LEFT DOUBLE (SLDA)

The SHIFT LEFT DOUBLE instruction shifts the 63 numeric bits of an even-odd register pair to the left, leaving the sign bit unchanged. Thus, the instruction performs an algebraic left shift of a 64-bit signed binary integer.

For example, if the contents of registers 2 and 3 are:

```
00 7F 0A 72    FE DC BA 98 =
00000000 01111111 00001010 01110010
11111110 110111100 10111010 100110002
```

The instruction:

Machine Format

Op Code	R <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
8F	2		0 01F

Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(B<sub>2</sub>)

---

SLDA 2,31(0)

results in registers 2 and 3 both being left-shifted 31 bit positions, so that their new contents are:

7F 6E 5D 4C 00 00 00 00 =  
01111111 01101110 01011101 01001100  
00000000 00000000 00000000 00000000<sub>2</sub>

Because significant bits are shifted out of bit position 1 of register 2, overflow is indicated by setting condition code 3, and, if the fixed-point-overflow mask bit in the PSW is one, a fixed-point-overflow program interruption occurs.

## SHIFT LEFT SINGLE (SLA)

The SHIFT LEFT SINGLE instruction is similar to SHIFT LEFT DOUBLE, except that it shifts only the 31 numeric bits of a single register. Therefore, this instruction performs an algebraic left shift of a 32-bit signed binary integer.

For example, if the contents of register 2 are:

00 7F 0A 72 = 00000000 01111111 00001010 01110010<sub>2</sub>

The instruction:

Machine Format

Op Code R<sub>1</sub> B<sub>2</sub> D<sub>2</sub>  

8B	2	///	0	008
----	---	-----	---	-----

Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(B<sub>2</sub>)

---

SLA 2,8(0)

results in register 2 being shifted left eight bit positions so that its new contents are:

7F 0A 72 00 = 01111111 00001010 01110010 00000000<sub>2</sub>

Condition code 2 is set to indicate that the result is greater than zero.

If a left shift of nine places had been specified, a significant bit would have been shifted out of bit position 1. Condition code 3 would have been set to

indicate this overflow and, if the fixed-point-overflow mask bit in the PSW were one, a fixed-point overflow interruption would have occurred.

## STORE CHARACTERS UNDER MASK (STCM)

STORE CHARACTERS UNDER MASK (STCM) may be used to place selected bytes from a register into storage. For example, if it is desired to store a three-byte address from general register 8 into location FIELD3, assume:

Machine Format

Op Code R<sub>1</sub> M<sub>3</sub> S<sub>2</sub>  

BE	8	7	* * *
----	---	---	-------

Register Format

Op Code R<sub>1</sub>,M<sub>3</sub>,S<sub>2</sub>

---

STCM 8,B'0111',FIELD3

Register 8: 12 34 56 78  
FIELD3 (before): not significant  
FIELD3 (after): 34 56 78

As another example:

Machine Format

Op Code R<sub>1</sub> M<sub>3</sub> S<sub>2</sub>  

BE	9	5	* * *
----	---	---	-------

Register Format

Op Code R<sub>1</sub>,M<sub>3</sub>,S<sub>2</sub>

---

STCM 9,B'0101',FIELD2

Register 9: 01 23 45 67  
FIELD2 (before): not significant  
FIELD2 (after): 23 67

## STORE MULTIPLE (STM)

Assume that the contents of general registers 14, 15, 0, and 1 are to be stored in consecutive four-byte fields starting with location 4050 and that:

Register 14 contains 00 00 25 63.

Register 15 contains 00 01 27 36.

Register 0 contains 12 43 00 62.

Register 1 contains 73 26 12 57.

Register 6 contains 00 00 40 00.

The initial contents of locations 4050-405F are not significant.

The STORE MULTIPLE instruction allows the use of just one instruction to store the contents of the four registers:

Machine Format

Op Code	R <sub>1</sub>	R <sub>3</sub>	B <sub>2</sub>	D <sub>2</sub>
90	E	1	6	050

Assembler Format

Op Code R<sub>1</sub>,R<sub>3</sub>,D<sub>2</sub>(B<sub>2</sub>)

STM 14,1,X'50'(6)

After the instruction is executed:

Locations 4050-4053 contain 00 00 25 63.

Locations 4054-4057 contain 00 01 27 36.

Locations 4058-405B contain 12 43 00 62.

Locations 405C-405F contain 73 26 12 57.

## TEST UNDER MASK (TM)

The TEST UNDER MASK instruction examines selected bits of a byte and sets the condition code accordingly. For example, assume that:

Storage location 9999 contains FB.

Register 7 contains 00 00 99 90.

Assume the instruction to be:

Machine Format

Op Code	I <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>
91	C3	7	009

Assembler Format

Op Code D<sub>1</sub>(B<sub>1</sub>),I<sub>2</sub>

TM 9(7),B'11000011'

The instruction tests only those bits of the byte in storage for which the mask bits are ones:

FB = 1111 1011<sub>2</sub>

Mask = 1100 0011<sub>2</sub>

Test = 11xx xx11<sub>2</sub>

Condition code 3 is set: all selected bits in the test result are ones. (The bits marked "x" are ignored.)

If location 9999 had contained B9, the test would have been:

B9 = 1011 1001<sub>2</sub>

Mask = 1100 0011<sub>2</sub>

Test = 10xx xx01<sub>2</sub>

Condition code 1 is set: the selected bits are both zeros and ones.

If location 9999 had contained 3C, the test would have been:

3C = 0011 1100<sub>2</sub>

Mask = 1100 0011<sub>2</sub>

Test = 00xx xx00<sub>2</sub>

Condition code 0 is set: all selected bits are zeros.

**Note:** Storage location 9999 remains unchanged.

## TRANSLATE (TR)

The TRANSLATE instruction can be used to translate data from any character code to any other desired code, provided that each character code consists of eight bits or fewer. An appropriate translation table is required in storage.

In the following example, EBCDIC code is translated to ASCII code. The first step is to create a 256-byte table in storage locations 1000-10FF. This table contains the characters of the ASCII code in the sequence of the binary representation of the EBCDIC code; that is, the ASCII representation of a

character is placed in storage at the starting address of the table plus the binary value of the EBCDIC representation of the same character.

For simplicity, the example shows only the part of the table containing the decimal digits:

10F0	10F9
30   31   32   33   34   35   36   37   38   39	

Assume that the four-byte field at storage location 2100 contains the EBCDIC code for the digits 1984:

Locations 2100-2103 contain F1 F9 F8 F4.

Register 12 contains 00 00 21 00.

Register 15 contains 00 00 10 00.

As the instruction:

Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
DC	03	C	000	F	000

Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

---

TR 0(4,12),0(15)

is executed, the binary value of each EBCDIC byte is added to the starting address of the table, and the resulting address is used to fetch an ASCII byte:

Table starting address: 1000  
First EBCDIC byte: F1

---

Address of ASCII byte: 10F1

After execution of the instruction:

Locations 2100-2103 contain 31 39 38 34.

Thus, the ASCII code for the digits 1984 has replaced the EBCDIC code in the four-byte field at storage location 2100.

## TRANSLATE AND TEST (TRT)

The TRANSLATE AND TEST instruction can be used to scan a data field for characters with a special meaning. To indicate which characters have a special

meaning, a table similar to the one used for the TRANSLATE instruction is set up, except that zeros in the table indicate characters without any special meaning and nonzero values indicate characters with a special meaning.

Figure A-4 on page A-34 has been set up to distinguish alphabetic characters (A to Z and 0 to 9) from blanks, certain special symbols, and all other characters which are considered invalid. EBCDIC coding is assumed. The 256-byte table is assumed stored at locations 2000-20FF.

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
200	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
201	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
202	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
203	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
204	04	40	40	40	40	40	40	40	40	40	40	40	08	40	0C	10
205	14	40	40	40	40	40	40	40	40	40	40	40	18	1C	20	40
206	24	28	40	40	40	40	40	40	40	40	40	2C	40	40	40	40
207	40	40	40	40	40	40	40	40	40	40	40	30	34	38	3C	40
208	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
209	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
20A	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
20B	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
20C	40	00	00	00	00	00	00	00	00	00	40	40	40	40	40	40
20D	40	00	00	00	00	00	00	00	00	00	40	40	40	40	40	40
20E	40	40	00	00	00	00	00	00	00	00	40	40	40	40	40	40
20F	00	00	00	00	00	00	00	00	00	00	40	40	40	40	40	40

**Note:** If the character codes in the statement being translated occupy a range smaller than 00 through FF<sub>16</sub>, a table of fewer than 256 bytes can be used.

Figure A-4. Translate and Test Table

The table entries for the alphabetic characters in EBCDIC are 00; thus, the letter A (code C1) corresponds to byte location 20C1, which contains 00.

The 15 special symbols have nonzero entries from 04<sub>16</sub> to 3C<sub>16</sub> in increments of 4. Thus, the blank (code 40) has the entry 04<sub>16</sub>, the period (code 4B) has the entry 08<sub>16</sub>, and so on.

All other table positions have the entry 40<sub>16</sub> to indicate an invalid character.

The table entries are chosen so that they may be used to select one of a list of 16 words containing

addresses of different routines to be entered for each special symbol or invalid character encountered during the scan.

Assume that this list of 16 branch addresses is stored at locations 3004-3043.

Starting at storage location CA80, there is the following sequence of  $21_{10}$  EBCDIC characters, where "b" stands for a blank.

Locations CA80-CA94:  
UNPKbPROUT(9),WORD(5)

Also assume:

Register 1 contains 00 00 CA 7F.

Register 2 contains 00 00 30 00.

Register 15 contains 00 00 20 00.

As the instruction:

Machine Format

Op Code	L	$B_1$	$D_1$	$B_2$	$D_2$
DD	14	1	001	F	000

Assembler Format

Op Code  $D_1(L, B_1), D_2(B_2)$

TRT 1(21,1),0(15)

is executed, the value of the first source byte, the EBCDIC code for the letter U, is added to the starting address of the table to produce the address of the table entry to be examined:

Table starting address	2000
First source byte (U)	E4
Address of table entry	20E4

Because zeros were placed in storage location 20E4, no special action occurs. The operation continues with the second and subsequent source bytes until it reaches the blank in location CA84. When this symbol is reached, its value is added to the starting address of the table, as usual:

Table starting address	2000
Source byte (blank)	40

Address of table entry	2040
------------------------	------

Because location 2040 contains a nonzero value, the following actions occur:

The address of the source byte, 00CA84, is placed in the rightmost 24 bits of register 1.

The table entry, 04, is placed in the rightmost eight bits of register 2, which now contains 00 00 30 04.

Condition code 1 is set (scan not completed).

The TRANSLATE AND TEST instruction may be followed by instructions to branch to the routine at the address found at location 3004, which corresponds to the blank character encountered in the scan. When this routine is completed, program control may return to the TRANSLATE AND TEST instruction to continue the scan, except that the length must first be adjusted for the characters already scanned.

For this purpose, the TRANSLATE AND TEST may be executed by the use of an EXECUTE instruction, which supplies the length specification from a general register. In this way, a complete statement scan can be performed with a single TRANSLATE AND TEST instruction used repeatedly by means of EXECUTE, and without modifying any instructions in storage. In the example, after the first execution of TRANSLATE AND TEST, register 1 contains the address of the last source byte translated. It is then a simple matter to subtract this address from the address of the last source byte (CA94) to produce a length specification. This length minus one is placed in the register that is referenced as the  $R_1$  field of the EXECUTE instruction. (Note that the length code in the machine format is one less than the total number of bytes in the field.) The second-operand address of the EXECUTE instruction points to the TRANSLATE AND TEST instruction, which is the same as illustrated above, except for the length (L) which is set to zero.

## UNPACK (UNPK)

Assume that storage locations 2501-2502 contain a signed-packed-decimal number that is to be unpacked and placed in storage locations 1000-1004. Also assume:

Register 12 contains 00 00 10 00.

Register 13 contains 00 00 25 00.

Storage locations 2501-2502 contain 12 3D.

The initial contents of storage locations 1000-1004 are not significant.

After the instruction:

Machine Format

Op Code	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
F3	4	1	C	000	D	001

Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

UNPK 0(5,12),1(2,13)

is executed, the storage locations 1000-1004 contain F0 F0 F1 F2 D3.

## UPDATE TREE (UPT)

See "Sorting Instructions" on page A-53.

## Decimal Instructions

(See Chapter 8, "Decimal Instructions" for a complete description of the decimal instructions.)

## ADD DECIMAL (AP)

Assume that the signed-packed-decimal number at storage locations 500-503 is to be added to the signed-packed-decimal number at locations 2000-2002. Also assume:

Register 12 contains 00 00 20 00.

Register 13 contains 00 00 05 00.

Storage locations 2000-2002 contain 38 46 0D (a negative number).

Storage locations 500-503 contain 01 12 34 5C (a positive number).

After the instruction:

Machine Format

Op Code	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
FA	2	3	C	000	D	000

Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

AP 0(3,12),0(4,13)

is executed, the storage locations 2000-2002 contain 73 88 5C; condition code 2 is set to indicate that the result is greater than zero. Note that:

1. Because the two numbers had different signs, they were in effect subtracted.
2. Although the second operand is longer than the first operand, no overflow interruption occurs because the result can be entirely contained within the first operand.

## COMPARE DECIMAL (CP)

Assume that the signed-packed-decimal contents of storage locations 700-703 are to be algebraically compared with the signed-packed-decimal contents of locations 500-502. Also assume:

Register 12 contains 00 00 06 00.

Register 13 contains 00 00 03 00.

Storage locations 700-703 contain 17 25 35 6D.

Storage locations 500-502 contain 72 14 2D.

After the instruction:

Machine Format

Op Code	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
F9	3	2	C	100	D	200

Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

CP X'100'(4,12),X'200'(3,13)

is executed, condition code 1 is set, indicating that the first operand (the contents of locations 700-703) is less than the second.

## DIVIDE DECIMAL (DP)

Assume that the signed-packed-decimal number at storage locations 2000-2004 (the dividend) is to be divided by the signed-packed-decimal number at locations 3000-3001 (the divisor). Also assume:

Register 12 contains 00 00 20 00.

Register 13 contains 00 00 30 00.

Storage locations 2000-2004 contain 01 23 45 67 8C.

Storage locations 3000-3001 contain 32 1D.

After the instruction:

Machine Format

Op Code	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
FD	4	1	C	000	D	000

Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

DP 0(5,12),0(2,13)

is executed, the dividend is entirely replaced by the signed quotient and remainder, as follows:

2000	2004
Locations 2000-2004 38 46 0D 01 8C	
quotient	remainder

### Notes:

- Because the dividend and divisor have different signs, the quotient receives a negative sign.
- The remainder receives the sign of the dividend and the length of the divisor.
- If an attempt were made to divide the dividend by the one-byte field at location 3001, the quotient would be too long to fit within the four bytes allotted to it. A decimal-divide exception would exist, causing a program interruption.

## EDIT (ED)

Before data in the signed-packed-decimal or unsigned-packed-decimal format can be used in a

printed report, digits and signs must be converted to printable characters. Moreover, punctuation marks, such as commas and decimal points, may have to be inserted in appropriate places. The highly flexible EDIT instruction performs these functions in a single instruction execution.

This example shows step-by-step one way that the EDIT instruction can be used. The field to be edited (the source) is four bytes long; it is edited against a pattern 13 bytes long. The following symbols are used:

Symbol	Meaning
b (Hexadecimal 40)	Blank character
( (Hexadecimal 21)	Significance starter
d (Hexadecimal 20)	Digit selector

Assume that register 12 contains:

00 00 10 00

and that the source and pattern fields are:

### Source

1200	1203
02 57 42 6C	

### Pattern

1000	100C
40 20 20 6B 20 21 20 4B 20 20 40 C3 D9	
b d d , d ( d . d d b C R	

Execution of the instruction:

Machine Format

Op Code	L	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
DE	0C	C	000	C	200

### Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

ED 0(13,12),X'200'(12)

alters the pattern field as follows:

Pattern	Digit	Significance Indicator (Before/After)	Rule	Location 1000-100C
b		off/off	leave(1)	bdd,d(d.ddbCR
d	0	off/off	fill	bbd,d(d.ddbCR
d	2	off/on(2)	digit	bb2,d(d.ddbCR
,		on/on	leave	same
d	5	on/on	digit	bb2,5(d.ddbCR
(	7	on/on	digit	bb2,57d.ddbCR
d	4	on/on	digit	bb2,574.ddbCR
.		on/on	leave	same
d	2	on/on	digit	bb2,574.2dbCR
d	6+	on/off(3)	digit	bb2,574.26bCR
b		off/off	fill	same
C		off/off	fill	bb2,574.26bbR
R		off/off	fill	bb2,574.26bbb

Notes:

1. This character is the fill byte.
2. First nonzero decimal source digit turns on significance indicator.
3. Plus sign in the four rightmost bits of the byte turns off significance indicator.

Thus, after the instruction is executed, the pattern field contains the result as follows:

### Pattern

1000	100C
40 40 F2 6B F5 F7 F4 4B F2 F6 40 40 40 b b 2 , 5 7 4 . 2 6 b b b	

This pattern field prints as:

2,574.26

The source field remains unchanged. Condition code 2 is set because the number was greater than zero.

If the number in the source field is changed to the negative number 00 00 02 6D and the original pattern is used, the edited result this time is:

### Pattern

1000	100C
40 40 40 40 40 40 F0 4B F2 F6 40 C3 D9 b b b b b b 0 . 2 6 b C R	

This pattern field prints as:

### 0.26 CR

The significance starter forces the significance indicator to the on state and hence causes a leading zero and the decimal point to be preserved. Because the minus-sign code has no effect on the significance indicator, the characters CR are printed to show a negative (credit) amount.

Condition code 1 is set (number less than zero).

## EDIT AND MARK (EDMK)

The EDIT AND MARK instruction may be used, in addition to the functions of EDIT, to insert a currency symbol, such as a dollar sign, at the appropriate position in the edited result. Assume the same source in storage locations 1200-1203, the same pattern in locations 1000-100C, and the same contents of general register 12 as for the EDIT instruction above. The previous contents of general register 1 (GR1) are not significant; a LOAD ADDRESS instruction is used to set up the first digit position that is forced to print if no significant digits occur to the left.

The instructions:

LA	1,6(0,12)	Load address of forced significant digit into GR1
EDMK	0(13,12),X'200'(12)	Leave address of first significant digit in GR1
BCTR	1,0	Subtract 1 from address in GR1
MVI	0(1),C '\$'	Store dollar sign at address in GR1

produce the following results for the two examples under EDIT:

### Pattern

1000	100C
40 5B F2 6B F5 F7 F4 4B F2 F6 40 40 40 b \$. 2 , 5 7 4 . 2 6 b b b	

This pattern field prints as:

\$2,574.26

Condition code 2 is set to indicate that the number edited was greater than zero.

## Pattern

1000	100C
40 40 40 40 40 5B F0 4B F2 F6 40 C3 D9	b b b b \$ 0 . 2 6 b C R

This pattern field prints as:

\$0.26 CR

Condition code 1 is set because the number is less than zero.

## MULTIPLY DECIMAL (MP)

Assume that the signed-packed-decimal number in storage locations 1202-1204 (the multiplicand) is to be multiplied by the signed-packed-decimal number in locations 500-501 (the multiplier).

	1202	1204
Multiplicand	38 46 0D	
Multiplier	500 501	
	32 1D	

The multiplicand must first be extended to have at least two bytes of leftmost zeros, corresponding to the multiplier length, so as to avoid a data exception during the multiplication. ZERO AND ADD can be used to move the multiplicand into a longer field. Assume:

Register 4 contains 00 00 12 00.

Register 6 contains 00 00 05 00.

Then execution of the instruction:

ZAP X'100'(5,4),2(3,4)

sets up a new multiplicand in storage locations 1300-1304:

	1300	1304
Multiplicand (new)	00 00 38 46 0D	

Now, after the instruction:

## Machine Format

Op Code	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
FC	4	1	4	100	6	000

## Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

MP X'100'(5,4),0(2,6)

is executed, storage locations 1300-1304 contain the product: 01 23 45 66 0C.

## SHIFT AND ROUND DECIMAL (SRP)

The SHIFT AND ROUND DECIMAL (SRP) instruction can be used for shifting decimal numbers in storage to the left or right. When a number is shifted right, rounding can also be done.

### Decimal Left Shift

In this example, the contents of storage location FIELD1 are shifted three places to the left, effectively multiplying the contents of FIELD1 by 1000. FIELD1 is six bytes long. The following instruction performs the operation:

## Machine Format

Op Code	L <sub>1</sub>	I <sub>3</sub>	S <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
F0	5	0	* * * *	0	003

## Assembler Format

Op Code S<sub>1</sub>(L<sub>1</sub>),S<sub>2</sub>,I<sub>3</sub>

SRP FIELD1(6),3,0

FIELD1 (before): 00 01 23 45 67 8C

FIELD1 (after): 12 34 56 78 00 0C

The second-operand address in this instruction specifies the shift amount (three places). The rounding digit, I<sub>3</sub>, is not used in a left shift, but it must be a valid decimal digit. After execution, condition code 2 is set to show that the result is greater than zero.

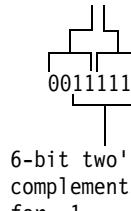

### Decimal Right Shift

In this example, the contents of storage location FIELD2 are shifted one place to the right, effectively

dividing the contents of FIELD2 by 10 and discarding the remainder. FIELD2 is five bytes in length. The following instruction performs this operation:

#### Machine Format

Op Code	$L_1$	$I_3$	$S_1$	$B_2$	$D_2$
F0	4	0	* * * *	0	03F

6-bit two's complement for -1

#### Assembler Format

Op Code  $S_1(L_1), S_2, I_3$

---

SRP FIELD2(5),64-1,0

FIELD 2 (before): 01 23 45 67 8C

FIELD 2 (after): 00 12 34 56 7C

In the SRP instruction, shifts to the right are specified in the second-operand address by negative shift values, which are represented as a six-bit value in two's complement form.

The six-bit two's complement of a number, n, can be specified as  $64 - n$ . In this example, a right shift of one is represented as  $64 - 1$ .

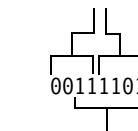

Condition code 2 is set.

#### Decimal Right Shift and Round

In this example, the contents of storage location FIELD3 are shifted three places to the right and rounded, in effect dividing by 1000 and rounding up. FIELD3 is four bytes in length.

#### Machine Format

Op Code	$L_1$	$I_3$	$S_1$	$B_2$	$D_2$
F0	3	5	* * * *	0	03D

6-bit two's complement for -3

#### Assembler Format

Op Code  $S_1(L_1), S_2, I_3$

---

SRP FIELD3(4),64-3,5

FIELD 3 (before): 12 39 60 0D

FIELD 3 (after): 00 01 24 0D

The shift amount (three places) is specified in the  $D_2$  field. The  $I_3$  field specifies a rounding digit of 5. The rounding digit is added to the last digit shifted out (which is a 6), and the carry is propagated to the left. The sign is ignored during the addition.

Condition code 1 is set because the result is less than zero.

#### Multiplying by a Variable Power of 10

Since the shift value specified by the SRP instruction specifies both the direction and amount of the shift, the operation is equivalent to multiplying the decimal first operand by 10 raised to the power specified by the shift value.

If the shift value is to be variable, it may be specified by the  $B_2$  field instead of the displacement  $D_2$  of the SRP instruction. The general register designated by  $B_2$  should contain the shift value (power of 10) as a signed binary integer.

A fixed scale factor modifying the variable power of 10 may be specified by using both the  $B_2$  field (variable part in a general register) and the  $D_2$  field (fixed part in the displacement).

The SRP instruction uses only the rightmost six bits of the effective address  $D_2(B_2)$  and interprets them as a six-bit signed binary integer to control the left or right shift as in the preceding shift examples.

## ZERO AND ADD (ZAP)

Assume that the signed-packed-decimal number at storage locations 4500-4502 is to be moved to locations 4000-4004 with four leading zeros in the result field. Also assume:

Register 9 contains 00 00 40 00.

Storage locations 4000-4004 contain 12 34 56 78 90.

Storage locations 4500-4502 contain 38 46 0D.

After the instruction:

Machine Format

Op Code	L <sub>1</sub>	L <sub>2</sub>	B <sub>1</sub>	D <sub>1</sub>	B <sub>2</sub>	D <sub>2</sub>
F8	4	2	9	000	9	500

Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

---

ZAP 0(5,9),X'500'(3,9)

is executed, the storage locations 4000-4004 contain 00 00 38 46 0D; condition code 1 is set to indicate a negative result without overflow.

Note that, because the first operand is not checked for valid sign and digit codes, it may contain any combination of hexadecimal digits before the operation.

---

## Hexadecimal-Floating-Point Instructions

(See Chapter 9, “Floating-Point Overview and Support Instructions” for a complete description of the hexadecimal-floating-point instructions.)

In this section, the abbreviations FPR0, FPR2, FPR4, and FPR6 stand for floating-point registers 0, 2, 4, and 6 respectively.

## ADD NORMALIZED (AD, ADR, AE, AER, AXR)

The ADD NORMALIZED instruction performs the addition of two HFP numbers and places the normal-

ized result in a floating-point register. Neither of the two numbers to be added must necessarily be in normalized form before addition occurs. For example, assume that:

FPR6 contains the unnormalized number C3 08 21 00 00 00 00 00 = -82.1<sub>16</sub> = -130.06<sub>10</sub> approximately.

Storage locations 2000-2007 contain the normalized number 41 12 34 56 00 00 00 00 = +1.23456<sub>16</sub> = +1.14<sub>10</sub> approximately.

Register 13 contains 00 00 20 00.

The instruction:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
7A	6	0	D	000

Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

---

AE 6,0(0,13)

performs the short-precision addition of the two operands, as follows.

The characteristics of the two numbers (43 and 41) are compared. Since the number in storage has a characteristic that is smaller by 2, it is right-shifted two hexadecimal digit positions. One guard digit is retained on the right. The fractions of the two numbers are then added algebraically:

	Fraction GD <sup>1</sup>
FPR6	-43 08 21 00
Shifted number from storage	+43 00 12 34 5
Intermediate sum	-43 08 0E CB B
Left-shifted sum	-42 80 EC BB

<sup>1</sup> Guard digit

Because the intermediate sum is unnormalized, it is left-shifted to form the normalized HFP number -80.ECBB<sub>16</sub> = -128.92<sub>10</sub> approximately. Combining the sign with the characteristic, the result is C2 80 EC BB, which replaces the left half of FPR6. The right half of FPR6 and the contents of storage locations 2000-2007 are unchanged. Condition code 1 is set to indicate a result less than zero.

If the long-precision instruction AD were used, the result in FPR6 would be C2 80 EC BA A0 00 00 00. Note that use of the long-precision instruction would avoid a loss of precision in this example.

## ADD UNNORMALIZED (AU, AUR, AW, AWR)

The ADD UNNORMALIZED instruction operates the same as the ADD NORMALIZED instruction, except that the final result is not normalized. For example, using the same operands as in the example for ADD NORMALIZED, when the short-precision instruction:

Machine Format

Op Code	R <sub>1</sub>	X <sub>2</sub>	B <sub>2</sub>	D <sub>2</sub>
7E	6	0	D	000

Assembler Format

Op Code R<sub>1</sub>, D<sub>2</sub>(X<sub>2</sub>, B<sub>2</sub>)

AU 6,0(0,13)

is executed, the two numbers are added as follows:

		Fraction GD <sup>1</sup>
FPR6		-43 08 21 00
Shifted number from storage		+43 00 12 34 5
Intermediate sum		-43 08 0E CB B

<sup>1</sup> Guard digit

The guard digit participates in the addition but is discarded. The unnormalized sum replaces the left half of FPR6. Condition code 1 is set because the result is less than zero.

The truncated result in FPR6 (C3 08 0E CB 00 00 00 00) shows a loss of a significant digit when compared to the result of short-precision normalized addition.

## COMPARE (CD, CDR, CE, CER)

Assume that FPR4 contains 43 00 00 00 00 00 00 00 (zero), and FPR6 contains 35 12 34 56 78 9A BC DE (a positive number). The contents of the two registers are to be compared using a long-precision COMPARE instruction.

Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
29	4	6

Assembler Format

Op Code R<sub>1</sub>, R<sub>2</sub>

CDR 4,6

The number with the smaller characteristic, which is in register FPR6, is right-shifted 43 - 35 hex (67 - 53 decimal) or 14 digit positions, so that the two characteristics agree. The shifted number is 43 00 00 00 00 00 00 00, with a guard digit of one. Therefore, when the two numbers are compared, condition code 1 is set, indicating that operand 1 in FPR4 is less than operand 2 in FPR6.

If the example is changed to a second operand with a characteristic of 34 instead of 35, so that FPR6 contains 34 12 34 56 78 9A BC DE, the operand is right-shifted 15 positions, leaving all fraction digits and the guard digit as zeros. Condition code 0 is set, indicating equality. This example shows that two HFP numbers with different characteristics or fractions may compare equal if the numbers are unnormalized or zero.

As another example of comparing unnormalized HFP numbers, 41 00 12 34 56 78 9A BC compares equal to all numbers of the form 3F 12 34 56 78 9A BC 0X (X represents any hexadecimal digit). When the COMPARE instruction is executed, the two rightmost digits are shifted right two places, the 0 becomes the guard digit, and the X does not participate in the comparison.

However, when two normalized HFP numbers are compared, the relationship between numbers that compare equal is unique: each digit in one number must be the same as the corresponding digit in the other number.

## DIVIDE (DD, DDR, DE, DER)

Assume that the first operand (the dividend) is in FPR2 and the second operand (the divisor) in FPR0. If the operands are in the short-precision format, the resulting quotient is returned to FPR2 by the instruction:

## Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
3D	2	0

## Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

---

DER 2,0

Several examples of short-precision HFP division, with the dividend in FPR2 and the divisor in FPR0, are shown below. For case A, the result, which replaces the dividend, is obtained in the following steps.

$$\begin{array}{r}
 7.2522F \\
 .123400 \overline{) .821000} \\
 7F6C00 \\
 \underline{2A400\ 0} \\
 24680\ 0 \\
 \underline{5D80\ 00} \\
 5B04\ 00 \\
 \underline{27C\ 000} \\
 246\ 800 \\
 \underline{35\ 8000} \\
 24\ 6800 \\
 \underline{11\ 18000} \\
 11\ 10C00 \\
 \hline
 7400
 \end{array}$$

Case	FPR2 Before (Dividend)	FPR0 (Divisor)	FPR2 After (Quotient)
A	-43 082100	+43 001234	-42 72522F
B	+42 101010	+45 111111	+3D F0F0F0
C	+48 30000F	+41 400000	+47 C0003C
D	+48 30000F	+41 200000	+48 180007
E	+48 180007	+41 200000	+47 C00038

Case C shows a number being divided by 4.0. Case D divides the same number by 2.0, and case E divides the result of case D again by 2.0. The results of cases C and E differ in the rightmost hexadecimal digit position, which illustrates an effect of result truncation.

## HALVE (HDR, HER)

HALVE produces the same result as HFP DIVIDE with a divisor of 2.0. Assume FPR2 contains the long-precision number +48 30 00 00 00 00 00 0F. The following HALVE instruction produces the result +48 18 00 00 00 00 00 07 in FPR2:

## Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
24	2	2

## Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

---

HDR 2,2

## MULTIPLY (MD, MDR, MDE, MDER, MXD, MXDR, MXR)

For this example, the following long-precision operands are in FPR0 and FPR2:

FPR0: -33 606060 60606060  
FPR2: -5A 200000 20000020

A long-precision product is generated by the instruction:

## Machine Format

Op Code	R <sub>1</sub>	R <sub>2</sub>
2C	0	2

## Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

---

MDR 0,2

If the operands were not already normalized, the instruction would first normalize them. It then generates an intermediate result consisting of the full 28-digit hexadecimal product fraction obtained by multiplying the 14-digit hexadecimal operand fractions, together with the appropriate sign and a characteristic that is the sum of the operand characteristics less 64 (40 hex):

The fraction multiplication is performed as follows:

$$\begin{array}{r}
 .60606060606060 \\
 .20000020000020 \\
 \hline
 COCO CO CO CO CO CO \\
 CO CO CO CO CO CO \\
 \hline
 .0C0C0C181818241818180C0C0C0
 \end{array}$$

Attaching the sign and characteristic to the fraction gives:

+4D 0C0C0C 18181824 1818180C 0C0C00

Because this intermediate product has a leading zero, it is then normalized. The truncated final result placed in FPR0 is:

+4C C0C0C1 81818241

## Hexadecimal-Floating-Point-Number Conversion

The following examples illustrate one method of converting between binary fixed-point numbers (32-bit signed binary integers) and normalized HFP numbers. Conversion must provide for the different representations used with negative numbers: the two's-complement form for signed binary integers, and the signed-absolute-value form for the fractions of HFP numbers.

### Fixed Point to Hexadecimal Floating Point

The method used here inverts the leftmost bit of the 32-bit signed binary integer, which is equivalent to adding  $2^{31}$  to the number and considering the result to be positive. This changes the number from a signed integer in the range  $2^{31} - 1$  through  $-2^{31}$  to an unsigned integer in the range  $2^{32} - 1$  through 0. After conversion to the long HFP format, the value  $2^{31}$  is subtracted again.

Assume that general register 9 (GR9) contains the integer -59 in two's-complement form:

GR9: FF FF FF C5

Further, assume two eight-byte fields in storage: TEMP, for use as temporary storage, and TWO31,

which contains the floating-point constant  $2^{31}$  in the following format:

TWO31: 4E 00 00 00 80 00 00 00

This is an unnormalized long HFP number with the characteristic 4E, which corresponds to a radix point (hexadecimal point) to the right of the number.

The following instruction sequence performs the conversion:

		Result
X	9,TWO31+4	GR9: 7FFF FFC5
ST	9,TEMP+4	TEMP: xxxx xxxx 7FFF FFC5
MVC	TEMP(4),TWO31	TEMP: 4E00 0000 7FFF FFC5
LD	2,TEMP	FPR2: 4E00 0000 7FFF FFC5
SD	2,TWO31	FPR2: C23B 0000 0000 0000

The EXCLUSIVE OR (X) instruction inverts the leftmost bit in general register 9, using the right half of the constant as the source for a leftmost one bit. The next two instructions assemble the modified number in an unnormalized long HFP format, using the left half of the constant as the plus sign, the characteristic, and the leading zeros of the fraction. LOAD (LD) places the number unchanged in floating-point register 2. The SUBTRACT NORMALIZED (SD) instruction performs the final two steps by subtracting  $2^{31}$  in HFP form and normalizing the result.

### Hexadecimal Floating Point to Fixed Point

The procedure described here consists basically in reversing the steps of the previous procedure. Two additional considerations must be taken into account. First: the HFP number may not be an exact integer. Truncating the excess hexadecimal digits on the right requires shifting the number one digit position farther to the right than desired for the final result, so that the units digit occupies the position of the guard digit. Second: the HFP number may have to be tested as to whether it is outside the range of numbers representable as a 32-bit signed binary integer.

Assume that floating-point register 6 contains the number  $59.25_{10} = 3B.4_{16}$  in normalized form:

FPR6: 42 3B 40 00 00 00 00 00

Further, assume three eight-byte fields in storage: TEMP, for use as temporary storage, and the constants  $2^{32}$  (TWO32) and  $2^{31}$  (TWO31R) in the following formats:

```
TW032: 4E 00 00 01 00 00 00 00
TW031R: 4F 00 00 00 08 00 00 00
```

The constant TWO31R is shifted right one more position than the constant TWO31 of the previous example, so as to force the units digit into the guard-digit position.

The following instruction sequence performs the integer truncation, range tests, and conversion to a signed binary integer in general register 8 (GR8):

		<b>Result</b>
SD	6,TWO31R	FPR6: C87F FFFF C500 0000
BC	11,OVERFLOW	Branch to overflow routine if result is greater than or equal to zero
AW	6,TWO32	FPR6: 4E00 0000 8000 003B
BC	4,OVERFLOW	Branch to overflow routine if result is less than zero
STD	6,TEMP	TEMP: 4E00 0000 8000 003B
XI	TEMP+4,X'80'	TEMP: 4E00 0000 0000 003B
L	8,TEMP+4	GR8: 0000 003B

The SUBTRACT NORMALIZED (SD) instruction shifts the fraction of the number to the right until it lines up with TWO31R, which causes the fraction digit 4 to fall to the right of the guard digit and be lost; the result of subtracting  $2^{31}$  from the remaining digits is renormalized. The result should be less than zero; if not, the original number was too large in the positive direction. The first BRANCH ON CONDITION (BC) performs this test.

The ADD UNNORMALIZED (AW) instruction adds  $2^{32}$ :  $2^{31}$  to correct for the previous subtraction and another  $2^{31}$  to change to an all-positive range. The second BC tests for a result less than zero, showing that the original number was too large in the negative direction. The unnormalized result is placed in temporary storage by the STORE (STD) instruction. There the leftmost bit of the binary integer is inverted by the EXCLUSIVE OR (XI) instruction to subtract  $2^{31}$ .

and thus convert the unsigned number to the signed format. The final result is loaded into GR8.

## Multiprogramming and Multiprocessing Examples

When two or more programs sharing common storage locations are being executed concurrently in a multiprogramming or multiprocessing environment, one program may, for example, set a flag bit in the common-storage area for testing by another program. It should be noted that the instructions AND (NI or NC), EXCLUSIVE OR (XI or XC), and OR (OI or OC) could be used to set flag bits in a multiprogramming environment; but the same instructions may cause program logic errors in a multiprocessing configuration where two or more CPUs can fetch, modify, and store data in the same storage locations simultaneously.

## Example of a Program Failure Using OR Immediate

Assume that two independent programs try to set different bits to one in a common byte in storage. The following example shows how the use of the instruction OR immediate (OI) can fail to accomplish this, if the programs are executed simultaneously on two different CPUs. One of the possible error situations is depicted.

Execution of instruction OI FLAGS,X'01' on CPU A	FLAGS	Execution of instruction OI FLAGS,X'80' on CPU B
Fetch FLAGS X'00'	X'00' X'00'	Fetch FLAGS X'00'
OR X'01' into X'00'	X'00' X'00'	OR X'80' into X'00'
Store X'01' into FLAGS	X'80' X'01'	Store X'80' into FLAGS

FLAGS should have value of X'81' following both updates.

The problem shown here is that the value stored by the OI instruction executed on CPU A overlays the value that was stored by CPU B. The X'80' flag bit was erroneously turned off, and the data is now invalid.

The COMPARE AND SWAP instruction has been provided to overcome this and similar problems.

## Conditional Swapping Instructions (CS, CDS)

The COMPARE AND SWAP (CS) and COMPARE DOUBLE AND SWAP (CDS) instructions can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas.

The following examples of the use of the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions illustrate the applications for which the instructions are intended. It is important to note that these are examples of functions that can be performed by programs while the CPU is enabled for interruption (multiprogramming) or by programs that are being executed in a multiprocessing configuration. That is, the routine allows a program to modify the contents of a storage location while the CPU is enabled, even though the routine may be interrupted by another program on the same CPU that will update the location, and even though the possibility exists that another CPU may simultaneously update the same location.

The COMPARE AND SWAP instruction first checks the value of a storage location and then modifies it only if the value is what the program expects; normally this would be a previously fetched value. If the value in storage is not what the program expects, then the location is not modified; instead, the current value of the location is loaded into a general register, in preparation for the program to loop back and try again. During the execution of COMPARE AND SWAP, no other CPU can perform a store access or interlocked-update access at the specified location.

To ensure successful updating of a common storage field by two or more CPUs, all updates must be done by means of an interlocked-update reference. See the programming notes of COMPARE AND SWAP for an example of how COMPARE AND SWAP can be unsuccessful due to an OR IMMEDIATE instruction executed by another CPU.

### Setting a Single Bit

The following instruction sequence shows how the COMPARE AND SWAP instruction can be used to set a single bit in storage to one. Assume that the first byte of a word in storage called "WORD" contains eight flag bits.

LA 6,X'80'	Put bit to be ORed into GR6
SLL 6,24	Shift left 24 places to align the byte to be ORed with the location of the flag bits within WORD
L 7,WORD	Fetch current flag values
RETRY LR 8,7	Load flags into GR8
OR 8,6	Set bit to one
CS 7,8,WORD	Store new flags if current flags unchanged, or re-fetch current flag values if changed
BC 4,RETRY	If new flags are not stored, try again

The format of the COMPARE AND SWAP instruction is:

#### Machine Format

Op Code	R <sub>1</sub>	R <sub>3</sub>	S <sub>2</sub>
BA	7	8	* * * *

#### Assembler Format

Op Code R<sub>1</sub>,R<sub>3</sub>,S<sub>2</sub>

CS 7,8,WORD

The COMPARE AND SWAP instruction compares the first operand (general register 7 containing the current flag values) to the second operand in storage (WORD) while no CPU other than the one executing the COMPARE AND SWAP instruction is permitted to perform a store access or interlocked-update access at the specified storage location.

If the comparison is successful, indicating that the flag bits have not been changed since they were fetched, the modified copy in general register 8 is stored into WORD. If the flags have been changed, the compare will not be successful, and their new values are loaded into general register 7.

The conditional branch (BC) instruction tests the condition code and reexecutes the flag-modifying instructions if the COMPARE AND SWAP instruction indicated an unsuccessful comparison (condition code 1). When the COMPARE AND SWAP instruction is successful (condition code 0), the flags contain valid data, and the program exits from the loop.

The branch to RETRY will be taken only if some other program modifies the contents of WORD. This

type of a loop differs from the typical “bit-spin” loop. In a bit-spin loop, the program continues to loop until the bit changes. In this example, the program continues to loop only if the value does change during each iteration. If a number of CPUs simultaneously attempt to modify a single location by using the sample instruction sequence, one CPU will fall through on the first try, another will loop once, and so on until all CPUs have succeeded.

## Updating Counters

In this example, a 32-bit counter is updated by a program using the COMPARE AND SWAP instruction to ensure that the counter will be correctly updated. The original value of the counter is obtained by loading the word containing the counter into general register 7. This value is moved into general register 8 to provide a modifiable copy, and general register 6 (containing an increment to the counter) is added to the modifiable copy to provide the updated counter value. The COMPARE AND SWAP instruction is used to ensure valid storing of the counter.

The program updating the counter checks the result by examining the condition code. The condition code 0 indicates a successful update, and the program can proceed. If the counter had been changed between the time that the program loaded its original value and the time that it executed the COMPARE AND SWAP instruction, the execution would have loaded the new counter value into general register 7 and set the condition code to 1, indicating an unsuccessful update. The program must then repeat the update sequence until the execution of the COMPARE AND SWAP instruction results in a successful update.

The following instruction sequence performs the above procedure:

```

LA 6,1      Put increment (1) into GR6
L 7,CNTR    Put original counter value
             into GR7
LOOP LR 8,7   Set up copy in GR8 to modify
AR 8,6       Increment copy
CS 7,8,CNTR  Update counter in storage
BC 4,LOOP    If original value had
             changed, update new value

```

The following shows two CPUs, A and B, executing this instruction sequence simultaneously: both CPUs attempt to add one to CNTR.

CPU A	CPU B	Comments
GR7	GR8	CNTR
	16	
16	16	CPU A loads GR7 and GR8 from CNTR
	16	CPU B loads GR7 and GR8 from CNTR
17	17	CPU B adds one to GR8
	17	CPU A adds one to GR8
	17	CPU A executes CS; successful match, store
	17	CPU B executes CS; no match, GR7 changed to CNTR value
	18	CPU B loads GR8 from GR7, adds one to GR8
	18	CPU B executes CS; successful match, store

## Bypassing Post and Wait

See the *MVS Programming: Authorized Assembler Services Guide* (SA22-7608) for details on bypassing the z/OS WAIT and POST routines.

## Lock/Unlock

When a common storage area larger than a double-word is to be updated, it is usually necessary to provide special interlocks to ensure that a single program at a time updates the common area. Such an area is called a serially reusable resource (SRR).

In general, updating a list, or even scanning a list, cannot be safely accomplished without first “freezing” the list. However, the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions can be used in certain restricted situations to perform queuing and list manipulation. Of prime importance is the capability to perform the lock/unlock functions and to provide sufficient queuing to resolve contentions, either in a LIFO or FIFO manner. The lock/unlock functions can then be used as the interlock mechanism for updating an SRR of any complexity.

The lock/unlock functions are based on the use of a “header” associated with the SRR. The header is the common starting point for determining the states of the SRR, either free or in use, and also is used for queuing requests when contentions occur. Conten-

tions are resolved using WAIT and POST. The general programming technique requires that the program that encounters a “locked” SRR must “leave a mark on the wall” indicating the address of an ECB on which it will WAIT. The “unlocking” program sees the mark and posts the ECB, thus permitting the waiting program to continue. In the two examples given, all programs using a particular SRR must use either the LIFO queuing scheme or the FIFO scheme; the two cannot be mixed. When more complex queuing is required, it is suggested that the queue for the SRR be locked using one of the two methods shown.

## Lock/Unlock with LIFO Queuing for Contentions

The header consists of a word, that is, a four-byte field aligned on a word boundary. The word can contain zero, a positive value, or a negative value.

- A zero value indicates that the serially reusable resource (SRR) is free.
- A negative value indicates that the SRR is in use but no additional programs are waiting for the SRR.
- A positive value indicates that the SRR is in use and that one or more additional programs are waiting for the SRR. Each waiting program is identified by an element in a chained list. The positive value in the header is the address of the element most recently added to the list.

Each element consists of two words. The first word is used as an ECB; the second word is used as a pointer to the next element in the list. A negative value in a pointer indicates that the element is the last element in the list. The element is required only if the program finds the SRR locked and desires to be placed in the list.

The following chart describes the action taken for LIFO LOCK and LIFO UNLOCK routines. The rou-

tines following the chart allow enabled code to perform the actions described in the chart.

Function	Action		
	Header Contains Zero	Header Contains Positive Value	Header Contains Negative Value
LIFO LOCK (the incoming element is at location A)	SRR is free. Set the header to a negative value. Use the SRR.	SRR is in use. Store the contents of the header into location A+4. Store address A into the header. WAIT; the ECB is at location A.	
LIFO UNLOCK	Error	Some program is waiting for the SRR. Move the pointer from the “last in” element into the header. POST; the ECB is in the “last in” element.	The list is empty. Store zeros into the header. The SRR is free.

### LIFO LOCK Routine:

Initial Conditions:

GR1 contains the address of the incoming element.

GR2 contains the address of the header.

```

LLOCK  SR    3,3      GR3 = 0
       ST    3,0(1)   Initialize the ECB
       LNR   0,1      GR0 = a negative value
TRYAGN CS    3,0,0(2) Set the header to a
               negative value if the
               header contains zeros
               BC    8,USE    Did the header contain
                           zeros?
               ST    3,4(1)   No, store the value of
                           the header into the
                           pointer in the in-
                           coming element
               CS    3,1,0(2) Store the address of
                           the incoming element
                           into the header
               LA    3,0(0)   GR3 = 0
               BC    7,TRYAGN Did the header get up-
                           dated?
WAIT   ECB=(1) Yes, wait for the re-
               source; the ECB is in
               the incoming element
USE    [Any instruction]

```

### **LIFO UNLOCK Routine:**

Initial Conditions:

GR2 contains the address of the header.

LUNLK	L 1,0(2)	GR1 = the contents of the header
A	LTR 1,1	Does the header contain a negative value?
	BC 4,B	
	L 0,4(1)	No, load the pointer from the last in element
	CS 1,0,0(2)	and store it in the header
	BC 7,A	Did the header get updated?
	POST (1)	Yes, post the last in element
	BC 15,EXIT	Continue
B	SR 0,0	The header contains a negative value; free
	CS 1,0,0(2)	the header and continue
EXIT	[Any instruction]	

Note that the LOAD instruction L 1,0(2) at location LUNLK would have to be CS 1,1,0(2) if it were not for the rule concerning storage-operand consistency. This rule requires the LOAD instruction to fetch a four-byte operand aligned on a word boundary such that, if another CPU changes the word being fetched by an operation which is also at least word-consistent, either the entire new or the entire old value of the word is obtained, and not a combination of the two. (See "Storage-Operand Consistency" on page 5-95.)

### **Lock/Unlock with FIFO Queuing for Contentions**

The header always contains the address of the most recently entered element. The header is originally initialized to contain the address of a posted ECB. Each program using the serially reusable resource (SRR) must provide an element regardless of whether contention occurs. Each program then enters the address of the element which it has provided into the header, while simultaneously it removes the address previously contained in the header. Thus, associated with any particular program attempting to use the SRR are two elements, called the "entered element" and the "removed element". The "entered element" of one program becomes the "removed element" for the immediately following program. Each program then waits on the removed element, uses the SRR, and then posts the entered element.

When no contention occurs, that is, when the second program does not attempt to use the SRR until after the first program is finished, then the POST of the first program occurs before the WAIT of the second program. In this case, the bypass-post and bypass-wait routines described in the preceding section are applicable. For simplicity, these two routines are shown only by name rather than as individual instructions.

In the example, the element need be only a single word, that is, an ECB. However, in actual practice, the element could be made larger to include a pointer to the previous element, along with a program identification. Such information would be useful in an error situation to permit starting with the header and chaining through the list of elements to find the program currently holding the SRR.

It should be noted that the element provided by the program remains pointed to by the header until the next program attempts to lock. Thus, in general, the entered element cannot be reused by the program. However, the removed element is available, so each program gives up one element and gains a new one. It is expected that the element removed by a particular program during one use of the SRR would then be used by that program as the entry element for the next request to the SRR.

It should be noted that, since the elements are exchanged from one program to the next, the elements cannot be allocated from storage that would be freed and reused when the program ends. It is expected that a program would obtain its first element and release its last element by means of the routines described in "Free-Pool Manipulation".

The following chart describes the action taken for FIFO LOCK and FIFO UNLOCK.

Function	Action
FIFO LOCK (the incoming element is at location A)	Store address A into the header. WAIT; the ECB is at the location addressed by the old contents of the header.
FIFO UNLOCK	POST; the ECB is at location A.

The following routines allow enabled code to perform the actions described in the previous chart.

### **FIFO Lock Routine:**

Initial conditions:

GR3 contains the address of the header.

GR4 contains the address, A, of the element currently owned by this program. This element becomes the entered element.

FLOCK	LR 2,4	GR2 now contains address of element to be entered
SR	1,1	GR1 = 0
ST	1,0(2)	Initialize the ECB
L	1,0(3)	GR1 = contents of the header
TRYAGN	CS 1,2,0(3)	Enter address A into header while remembering old contents of header into GR1; GR1 now contains address of removed element
BC	7,TRYAGN	Removed element becomes new currently owned element
LR	4,1	Removed element becomes new currently owned element
HSWAIT		Perform bypass-wait routine; if ECB already posted, continue; if not, wait; GR1 contains the address of the ECB
USE	[Any instruction]	

#### **FIFO Unlock Routine:**

Initial conditions:

GR2 contains the address of the removed element, obtained during the FLOCK routine.

GR5 contains 40 00 00 00<sub>16</sub>

FUNK	LR 1,2	Place address of entered element in GR1; GR1 = address of ECB to be posted
SR	0,0	GR0 = 0; GR0 has a post code of zero
OR	0,5	Set bit 1 of GR0 to one
HSPOST		Perform bypass-post routine; if ECB has not been waited on, then mark posted and continue; if it has been waited on, then post

CONTINUE [Any instruction]

## **Free-Pool Manipulation**

It is anticipated that a program will need to add and delete items from a free list without using the lock/unlock routines. This is especially likely since the lock/unlock routines require storage elements for queuing and may require working storage. The lock/unlock routines discussed previously allow simultaneous lock routines but permit only one unlock routine at a time. In such a situation, multiple additions and a single deletion to the list may all occur simultaneously, but multiple deletions cannot occur at the same time. In the case of a chain of pointers containing free storage buffers, multiple deletions along with additions can occur simultaneously. In this case, the removal cannot be done using the COMPARE AND SWAP instruction without a certain degree of exposure.

Consider a chained list of the type used in the LIFO lock/unlock example. Assume that the first two elements are at locations A and B, respectively. If one program attempted to remove the first element and was interrupted between the fourth and fifth instructions of the LUNK routine, the list could be changed so that elements A and C are the first two elements when the interrupted program resumes execution. The COMPARE AND SWAP instruction would then succeed in storing the value B into the header, thereby destroying the list.

The probability of the occurrence of such list destruction can be reduced to *near* zero by appending to the header a counter that indicates the number of times elements have been added to the list. The use of a 32-bit counter guarantees that the list will not be destroyed unless the following events occur, in the exact sequence:

1. An unlock routine is interrupted between the fetch of the pointer from the first element and the update of the header.
2. The list is manipulated, including the deletion of the element referenced in 1, and exactly  $2^{32}$  (or an integer multiple of  $2^{32}$ ) additions to the list are performed. Note that this takes on the order of days to perform in any practical situation.
3. The element referenced in 1 is added to the list.
4. The unlock routine interrupted in 1 resumes execution.

The following routines use such a counter in order to allow multiple, simultaneous additions and removals at the head of a chain of pointers.

The list consists of a doubleword header and a chain of elements. The first word of the header contains a pointer to the first element in the list. The second word of the header contains a 32-bit counter indicating the number of additions that have been made to the list. Each element contains a pointer to the next element in the list. A zero value indicates the end of the list.

The following chart describes the free-pool-list manipulation.

Function	Action	
	Header = 0,Count	Header = A,Count
ADD TO LIST (the incoming element is at location A)	Store the first word of the header into location A. Store the address A into the first word of the header. Decrement the second word of the header by one.	
DELETE FROM LIST	The list is empty.	Set the first word of the header to the value of the contents of location A. Use element A.

The following routines allow enabled code to perform the free-pool-list manipulation described in the above chart.

#### **ADD TO FREE LIST Routine:**

Initial Conditions:

GR2 contains the address of the element to be added.

GR4 contains the address of the header.

```

ADDQ  LM  0,1,0(4) GR0,GR1 = contents of
                  the header
TRYAGN ST  0,0(2)  Point the new element to
                  the top of the list
                  LR  3,1      Move the count to GR3
                  BCTR 3,0    Decrement the count
                  CDS  0,2,0(4) Update the header
                  BC  7,TRYAGN
  
```

#### **DELETE FROM FREE LIST Routine:**

Initial conditions:

GR4 contains the address of the header.

DELETQ	LM  2,3,0(4)	GR2,GR3 = contents of the header
TRYAGN	LTR 2,2	Is the list empty?
	BC  8,EMPTY	Yes, get help
	L  0,0(2)	No, GR0 = the pointer from the first element
	LR  1,3	Move the count to GR1
	CDS 2,0,0(4)	Update the header
	BC  7,TRYAGN	
USE	[Any instruction]	The address of the removed element is in GR2

Note that the LM (LOAD MULTIPLE) instructions at locations ADDQ and DELETQ would have to be CDS (COMPARE DOUBLE AND SWAP) instructions if it were not for the rule concerning storage-operand consistency. This rule requires the LOAD MULTIPLE instructions to fetch an eight-byte operand aligned on a doubleword boundary such that, if another CPU changes the doubleword being fetched by an operation which is also at least doubleword-consistent, either the entire new or the entire old value of the doubleword is obtained, and not a combination of the two. (See "Storage-Operand Consistency" on page 5-95.)

## **PERFORM LOCKED OPERATION (PLO)**

The PERFORM LOCKED OPERATION instruction can be used in a multiprogramming or multiprocessing environment to perform compare, load, compare-and-swap, and store operations on two or more contiguous locations that can be words or doublewords. The operations are performed as an atomic set of operations under the control of a lock that is held only for the duration of the execution of a single PERFORM LOCKED OPERATION instruction, as opposed to across the execution of multiple instructions. Since lock contention is resolved by the CPU and is very brief, the program need not include a method for dealing with the case when the lock to be used is held by a program being executed by another CPU. Also, there need be no concern that the program may be interrupted while it holds a lock, since PERFORM LOCKED OPERATION will complete its operation and release its lock before an interruption can occur.

PERFORM LOCKED OPERATION can be thought of as performing concurrent interlocked updates of multiple operands. However, the instruction does not actually perform any interlocked update, and a serially reusable resource cannot be updated predictably through the use of both PERFORM LOCKED OPERATION and conditional-swapping instructions (CS and CDS).

Following is an example of how PERFORM LOCKED OPERATION can be used to add an element at the beginning of a queue.

Assume the following variables associated with the queue: S, which is a sequence number that is incremented anytime the queue is changed; H (for head), which is the address of the first element on the queue; and C, which is a count of the number of elements on the queue. Assume a queue element contains a variable, F (for forward), which is the address of the next element on the queue. If a new element, N, is to be enqueued at the head of the queue, that can be done by setting F in N to H and then performing the following atomic set of operations:

$S+1 \rightarrow S$   
 $A(N) \rightarrow H$   
 $C+1 \rightarrow C$

where  $A(N)$  is the address of N.

The enqueueing of N can be done by means of the following steps:

1. Obtain consistent values of S, H, and C, meaning obtain S and obtain the H and C that are consistent with that value of S.
2. Store H in N.F.
3. By means of PLO.csdst (PERFORM LOCKED OPERATION performing compare and swap and double store), with S as the swap variable and H and C as the store variables, add one to S, set H to  $A(N)$ , and add one to C, provided that S still has the value obtained in step 1. If S has already been changed, go back to step 1.

Consistent values of S, H, and C cannot necessarily be obtained simply by using three LOAD instructions because a PERFORM LOCKED OPERATION instruction being executed by another CPU may have completed an update of S but not yet of H or C. In this case, the three LOAD instructions will obtain the

new S but the old H or C. However, as will be described, it may be possible to use three LOAD instructions.

If S is obtained while holding the lock, meaning by means of PERFORM LOCKED OPERATION, then H and C can be obtained by LOAD instructions since no other CPU can subsequently change H or C without changing S, as observed when the lock is held.

The parameter list used by the PLO.csdst is as follows, assuming the access-register mode is not used:

0	
8	
:	
48	
56	A(N)
64	
72	A(H)
80	
88	C+1
96	
104	A(C)

The program is as follows:

LA	RT,H	Initialize addresses in PL (T = temp)
ST	RT,PL+76	Op4 address (address of H)
LA	RT,C	
ST	RT,PL+108	Op6 address (address of C)
LA	RN,N	Address of N
ST	RN,PL+60	Initialize op3 in PL (address of N)
LA	R1,S	PLT address = address of S
<hr/>		
SR	RS,RS	Dummy S. CC1 will probably be set
SR	R0,R0	Function code 0 (compare and load)
PLO	RS,S,RS,S	Obtain S while holding lock
<hr/>		
LOOP	LA R0,16	Function code 16 (csdst)
	L RT,H	Consistent H
	ST RT,OFSTF(,RN)	OFSTF = offset of

		F in N
L	RT,C	Consistent C
LA	RT,1(,RT)	C+1
ST	RT,PL+92	Initialize op5 in PL (C+1)
LA	RSP,1(,RS)	RS/RSP = even/odd pair. S+1 in RSP
PLO	RS,S,0,PL	
BNZ	LOOP	Br if S changed (if CC not 0)

Note the following about the first PERFORM LOCKED OPERATION instruction (PLO.cl). If S is not zero (which is probably true), S (the second operand, op2) is loaded into RS (the first-operand comparison value, op1c). If S is zero, S (the fourth operand, op4) is loaded into RS (the third operand, op3). Either of these loads occurs while the lock is held. It is unnecessary to test the condition code to determine which load occurred.

The above program may be a simplification. If the queue has associated with it a variable, T (for tail), that is the address of the last element on the queue, and the queue is currently empty, T also must be set when N is added to the queue. This would require a different program using a compare-and-swap-and-triple-store operation.

If the queue is added to, deleted from, and rearranged by means of PERFORM LOCKED OPERATION instructions in which the sequence number, S, is always the second operand, then, since the definition of PERFORM LOCKED OPERATION specifies that the second operand is always stored last, the first PERFORM LOCKED OPERATION instruction in the above program can be replaced by a LOAD instruction. The three instructions within the dashed lines would be replaced by L RS,S.

---

## Sorting Instructions

### Tree Format

Two instructions, COMPARE AND FORM CODEWORD and UPDATE TREE, refer to a tree — a data structure with a specific format. A tree consists of some number (always odd) of consecutively numbered nodes. Node 1 is the root of the tree. Every node except the root has one parent node in the same tree. Every parent node has two son nodes.

Every even-numbered node is the *leftson* of its parent node, and every odd-numbered node (except node 1) is the *rightson* of its parent node. Division by two (ignoring remainder) of the node number gives the parent node number. Nodes with sons are also called internal nodes, and nodes without sons are called terminal nodes. Figure A-5 on page A-54 illustrates schematically a 21-node tree with arrows drawn from each parent node to each son node.

A tree is used for merging several sorted sequences of records into a single merged sequence of records. At each step in the merging process, there exists the initial part of the merged sequence and the remaining parts of each of the sorted sequences that are being merged. Each step consists in selecting the lowest record (the record with the lowest key when sorting in ascending sequence) from all of the as yet unmerged parts of the sorted sequences and adding it to the merged sequence. Each terminal node in the tree represents one of the sorted sequences. The number of internal nodes in the tree is one less than the number of sorted sequences. Each internal node conceptually contains one record from each of the sorted sequences but one; these are the lowest records, from all but one of the sorted sequences, that have not yet been added to the merged sequence. In addition, there is the lowest record from the one remaining sorted sequence. This additional record is compared and interchanged with nodes of the tree to select the record to be added next to the merged sequence. This processing begins with the parent of the terminal node that represents the one remaining sorted sequence, and it continues from that node along the path to the root of the tree. The selected record emerges from the root of the tree.

The tree may perhaps be most easily explained by considering each node to represent a comparison operation in an “elimination tournament” to find the lowest record. After the tournament has been completed, each node has an associated “loser” record which had a higher key in the comparison represented by that node. Besides a loser record at each node, there is one record (the “winner”) which is not associated with any node since it never compared high. The next step would be to introduce a new record from the same sorted sequence from which the winner record originated and replay the tournament with the new record in place of the former winner. It can be seen that it is unnecessary to do all the comparisons represented by all the nodes in the tree — most of them are unaffected by the new record replacing the former winner. In fact, it is suffi-

client to redo only those node comparisons in which the former winner record participated. Each new record is inserted into the tree at the terminal node that represents the sorted sequence containing the record. The use of the tree assumes that programming provides a method of remembering at which terminal node each winning record originated. The instruction UPDATE TREE allows for a new record to be inserted at a terminal node and the tree to be updated so that a new winner record is left in the general registers.

Rather than comparing the actual keys of records, much of the merge logic can be performed using “codewords” to represent a record key rather than referring to actual keys. The value of a codeword at a node in the tree depends not only on the record’s key but also on the key of the winning record in the last comparison at that node. The codeword consists of two parts:

1. Bits 16-31 contain the one’s complement of the first halfword in which the record key differs from that of the node’s winning record.
2. Bits 0-15 specify the byte offset of the halfword in this record’s key just beyond the halfword value (complemented) in bit positions 16-31.

When comparing records in the path of the last winner record, if the new record is also represented by a codeword resulting from a comparison with the last winner, all codewords in the update path are with respect to the same winner. When comparing such codewords, a high codeword represents a low key and vice versa. Thus, when codewords are unequal, a node entry with a high codeword (representing a low actual key) should move up the tree.

In the case of a tie value of codewords, it is necessary to refer to the actual keys. This is done by the instruction COMPARE AND FORM CODEWORD, which resolves the ambiguity and computes a new codeword for the high-key (loser) record.

The eight bytes at each node of a tree consist of (1) a codeword for this record, computed with respect to the last record which compared low against this record and (2) a parameter usable to locate this record, for example, a direct or indirect address.

The instruction UPDATE TREE is so defined that tree updating stops after equal codewords are detected and the tie-breaking instruction COMPARE AND

FORM CODEWORD can be used, after which UPDATE TREE can resume tree updating at the point where equal codewords were previously found.

COMPARE AND FORM CODEWORD may alternatively be used for merging in descending sequence. In that case, bits 16-31 of the codeword at a node contain the true value of the first halfword in which the record key differs from that of the node’s winning record. When the descending option of COMPARE AND FORM CODEWORD is used, the higher of two codewords represents the higher key.

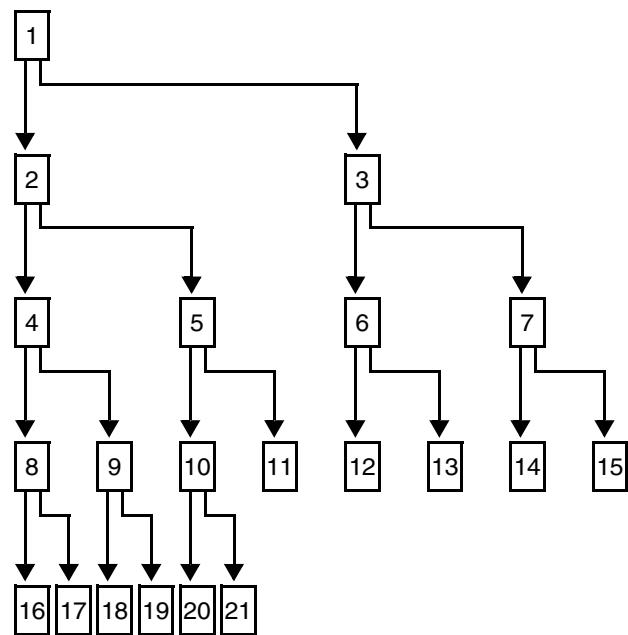

Figure A-5. Schematic Diagram of Merge Control Tree with 21 Nodes

## Example of Use of Sort Instructions

An example illustrates how the instructions UPDATE TREE and COMPARE AND FORM CODEWORD may be used in the merge operation within a sort program. A five-way merge requires a tree data structure with four internal nodes and five terminal-node positions. The schematic diagram shown later in this section illustrates such a tree, containing four internal nodes (not counting the dummy node) and five input sequences for a merge, one sequence at each terminal-node position. Each record in an input sequence in the diagram is indicated by its address. The actual record contents are shown in Figure A-7 on

page A-58. Each record contains 16 bytes, consisting of the following fields:

Byte Offset (hexadecimal)	Field
0-5	Six-byte record key.
6-7	Halfword node index specifying the input sequence of the next record of this input sequence.
8-B	Address of the next record in the same input sequence.
C-F	This chaining field is initially zero. At the completion of the merge, this field is to contain the address of the next record in the merged sequence.

The merge process forms a single sorted sequence from five input sequences, each of which is in sorted order. This process can be subdivided into three steps:

1. A priming step takes the first record from each of the five input sequences and places them in the tree data structure. For each record to be introduced into the tree, first its codeword value is computed with respect to the lowest possible key value of all zeros. This codeword, with a second word which contains the address of the actual record, forms a doubleword node value that can be placed at the appropriate node. After priming, the node values, one each from each of the five input sequences, will have been placed in the tree so that each of the four internal nodes contains one node value and the node value for a winner record has emerged from the root of the tree.
2. After each winner emerges from the tree, the main merge process is performed repeatedly. Each iteration introduces the node value for one new record into the tree and produces a node value for a new winner record. The tree plus the winner must at all times contain precisely one node value from each input sequence being merged. Therefore, the new node value that is introduced into the tree on each iteration must come from the same input sequence from which the winner node value in the preceding iteration originated.
3. When the node value for the last record of an input sequence emerges as a winner, there is no successor record from that input sequence to be introduced into the tree on the next iteration. Hence, the order of the merge must be reduced

by one for each such occurrence. This runout process will consist of one or more iterations for each of a four-way, three-way, two-way, and one-way merge. The onset of runout occurs in the example when it is found that the next input record from a sequence is lower than its predecessor (a sequence break).

The priming process is discussed next, and the state of the tree is shown after priming is complete. Then, a short program that uses the instructions UPDATE TREE and COMPARE AND FORM CODEWORD to perform the main merge is described. An abbreviated trace is then presented to show the status of the tree and certain general registers for 16 iterations of the main merge. The runout process is not discussed in this example.

Priming begins by forming the node value for the first record of each input sequence. The first word of the node value is the codeword formed by executing COMPARE AND FORM CODEWORD on a record key containing all binary zeros. The second word of the node value is the address of the record represented by that node value. The node values for the first record of each input sequence are:

Sequence Index	Node Values
28	0006 FFFC 0000 1030
30	0006 FFFF 0000 1040
38	0006 FFFA 0000 1050
40	0004 FFFE 0000 1080
48	0006 FFF0 0000 1060

In the example, the tree data structure is assumed to have base address X'1000', which is kept in general register 4 (to match the expected use in UPDATE TREE). Similarly, internal-node index values and input-sequence index values are always used from general register 5.

Although the tree-priming program is not part of this example, the UPDATE TREE instruction is used in creating it as follows. First, the codeword position for each internal node of the tree is initialized to all ones (X'FFFF FFFF'). This artifice fills the tree with dummy low records. Then, for each record in the table, (1) the sequence index is loaded into general register 5, (2) the node value is loaded into general registers 0 and 1, and (3) UPDATE TREE is executed. At the completion of this priming process, the tree-node contents in the example are as shown on line 0 of Figure A-9 on page A-60. The contents of

the general registers are as shown on the first line of Figure A-8 on page A-59.

The figure illustrating the program for the main merge is divided into three groups of columns, containing the absolute program, the general-register trace, and the symbolic program. The first part of the program extends from symbolic locations L1 through L2; it introduces a new record into the tree and executes an UPDATE TREE instruction. If no tied codewords are encountered in UPDATE TREE, then the BRANCH ON CONDITION instruction following UPDATE TREE loops back to L1 to introduce the next record into the tree. This BRANCH ON CONDITION instruction is suitable for use when UPDATE TREE operates in accordance with either its method 1 (setting condition code 1) or its method 2 (setting condition code 3). (The preceding sentence applies to 370-XA. In ESA/370 and ESA/390, UPDATE TREE operates in accordance with only method 2, which is not to say that it cannot set condition code 1. Method 2, but not method 1, tests for the condition that sets condition code 3.)

If UPDATE TREE encounters tied codewords, then the UPDATE TREE instruction is completed, the subsequent BRANCH ON CONDITION instruction does not branch, and control falls through to the second part of the program, which handles entries with tied codewords. This part then branches back to UPDATE TREE at L2, which resumes the tree updating. It is possible for tied codewords to be encountered at any level in the tree (or indeed at all levels), so that the tied-codeword part of the program may be entered up to three times for each record introduced.

The general-register trace for the first part of the main merge shows the contents of the first seven general registers after each instruction is executed during the first iteration. Note that the merged-chain field (at 1140) serves as the anchor for the merged-chain address chain through the records. The trace shows only the lower half of certain general registers, whose upper half is always zero.

Figure A-9 on page A-60 gives an abbreviated trace of the entire main merge of 16 records. For each record introduced into the tree, there are one or more lines (always an odd number) given in the figure to show the tree updating, which results finally in a winner in GR0 and GR1. The first line for each record shows the values of GR5, GR2, and GR3 before the first or only execution of UPDATE TREE. For the even-numbered lines, the storage updating by

UPDATE TREE of tree nodes is shown (read left to right to follow the order of swapping). For example, consider line 10 and the corresponding UPDATE TREE: since GR5 contains 28, the first storage node examined is 1010 (refer to the schematic diagram). Since the codeword in GR0 is 0004 FFFE (same as for GR2), which is less than that of the word at 1010 (0006 FFF0), the doubleword at 1010 is swapped with that in GR0 and GR1. A second comparison at 1008 in the same execution of UPDATE TREE causes another register-storage doubleword swap, which leaves the winner (record 1040) in GR1 at the completion of UPDATE TREE (see the column at the far right of Figure A-9 on page A-60).

When a codeword comparison is made which does not result in a tie or a swap (that is, when the storage-codeword value is low), an asterisk appears in the trace for that storage entry.

When equal codewords are found, the execution of UPDATE TREE is completed. The following line in each such case shows the result of the tied-codeword routine, which always stores a new codeword and may also store a new record address before branching back to L2 to execute UPDATE TREE again. In this line, the notation "loses" or "wins" means that the node loses or wins, respectively.

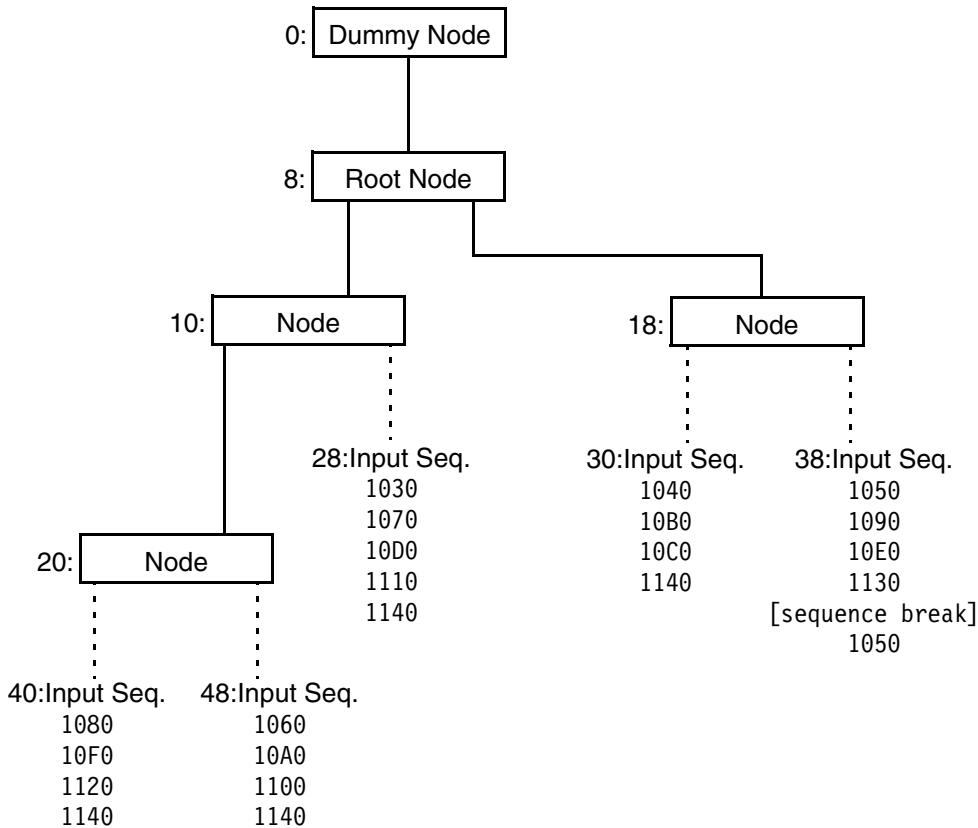

The tie-break trace part of Figure A-8 on page A-59 shows the treatment of the third record (that is, the first record for which UPDATE TREE encounters a tied codeword). This corresponds to line 31 in Figure A-9 on page A-60.

The following is a summary of the steps that are needed to use this example for verification purposes:

1. Initialize storage as follows:
  - a. 1008 through 102F from line 0 of Figure A-9 on page A-60
  - b. 1030 through 114F from Figure A-7 on page A-58
  - c. 1150 through 1189 from Figure A-8 on page A-59
2. Initialize GRs per first line in Figure A-8 and trace first record per Figure A-8.
3. Trace to completion of each UPT or BC 15,L2 (once for each line of Figure A-9). A detailed trace of the GRs for the tied-codeword part of

line 31 of Figure A-9 is given in the lower part of Figure A-8.

4. Verify that addresses in the chain beginning at 103C and continuing through 114C are as shown in the right-hand column of Figure A-7.

**Note:** Each node and input sequence is identified by a number which is the hexadecimal node index. Each input sequence is given as a list of record addresses (also in hexadecimal).

166				No comp									00020000	1130
170	38	00020000	1050	Branch										

**Explanation:**

<sup>1</sup> Line 0 shows the values in the tree after it is primed.

\* Means no swap.

\*\* Means no swap if UPDATE TREE method 1 is used or no examination if UPDATE TREE method 2 is used. Only method 2 is included in ESA/370 and ESA/390.

CC = 0 UPDATE TREE finds a tie and sets condition code 0.

Loses The tied-codeword routine finds that the node loses.

Wins The tied-codeword routine finds that the node wins.

Equal The tied-codeword routine finds that the keys are equal.

Branch Branches to terminate at 118A on sequence break.

No comp No compare.

Figure A-9. Abbreviated Trace of Main Merge Processing

## Appendix B. Lists of Instructions

The following figures list instructions by name, mnemonic, and operation code. Some models may offer instructions that do not appear in the figures, such as those provided for assists or as part of special or custom features.

The operation code for the interpretive execution facility is not included in this appendix. See the publication *IBM System/370 Extended Architecture Interpretive Execution*, SA22-7095, for the operation code associated with that facility.

The operation code 00 hex with a two-byte instruction format is allocated for use by the program when an indication of an invalid operation is required. Operation code 00 hex will never be assigned to an instruction implemented in the CPU.

### ***Explanation of Symbols in “Characteristics” and “Page” Columns:***

\$	Causes serialization.	B‡	B <sub>2</sub> field designates an access register when bit 63 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 63 of GR0 is one, and bits 56-57 of GR0 are 01 binary.
¢	Causes serialization and checkpoint synchronization.	BP	B <sub>2</sub> field designates an access register when PSW bits 16 and 17 have the value 01.
¢ <sup>1</sup>	Causes serialization and checkpoint synchronization when the M <sub>1</sub> and R <sub>2</sub> fields contain all ones and all zeros, respectively.	C	Condition code is set.
¢ <sup>2</sup>	Causes serialization and checkpoint synchronization when the state entry to be unstacked is a program-call state entry.	CS	Compare-and-swap-and-store facility.
A	Access exceptions for logical addresses.	CT	Configuration-topology facility.
A <sup>1</sup>	Access exceptions; not all access exceptions may occur; see instruction description for details.	D2	DAT-enhancement facility 2.
AI	Access exceptions for instruction address.	Da	AFP-register data exception.
AS	ASN-translation-specification and special-operation exceptions.	Db	BFP-instruction data exception.
AT	ASN-translation-specification exception.	Dd	Decimal-operand data exception.
B	PER branch event.	DE	DAT-enhancement facility.
B <sub>1</sub>	B <sub>1</sub> field designates an access register in the access-register mode.	DF	Decimal-overflow exception.
B <sub>2</sub>	B <sub>2</sub> field designates an access register in the access-register mode.	DK	Decimal-divide exception.
B†	B <sub>1</sub> field designates an access register when bit 47 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 47 of GR0 is one, and bits 40-41 of GR0 are 01 binary.	DM	Depending on the model, DIAGNOSE may generate various program exceptions and may change the condition code.
		DT	DFP-instruction data exception.
		E	E instruction format.
		E2	Extended-translation facility 2.
		E3	Extended-translation facility 3.
		ED	Enhanced-DAT facility.
		EI	Extended-immediate facility.
		EO	HFP-exponent-overflow exception.
		ES	Expanded-storage facility.
		ET	Extract-CPU-time facility.
		EU	HFP-exponent-underflow exception.
		EX	Execute exception.
		FC	Designation of access registers depends on the function code of the instruction.
		FG	FPR-GR-transfer facility.
		FK	HFP-floating-point-divide exception.
		FL	Store-facility-list-extended facility.
		FS	Floating-point-support-sign-handling facility.
		G0	Instruction execution includes the implied use of general register 0.
		G1	Instruction execution includes the implied use of general register 1.
		G2	Instruction execution includes the implied use of general register 2.

G4	Instruction execution includes the implied use of general register 4.	RM	R <sub>1</sub> field designates an access register in the access-register mode, and access-register 1 also is used in the access-register mode.
GE	General-instructions-extension facility.	RR	RR instruction format.
GM	Instruction execution includes the implied use of multiple general registers.	RRE	RRE instruction format.
GS	Instruction execution includes the implied use of general register 1 as the subsystem-identification word.	RRF	RRF instruction format.
HM	HFP-multiply-add/subtract facility.	RRR	RRR instruction format.
I	I instruction format.	RS	RS instruction format.
I1	Access register 1 is implicitly designated in the access-register mode.	RSL	RSL instruction format.
I4	Access register 4 is implicitly designated in the access-register mode.	RSY	RSY instruction format.
IF	Fixed-point-overflow exception.	RX	RX instruction format.
II	Interruptible instruction.	RXE	RXE instruction format.
IK	Fixed-point-divide exception.	RXF	RXF instruction format.
IS	Interruptible instruction and special-operation exception.	RXY	RXY instruction format.
L	New condition code is loaded.	S	S instruction format.
LD	Long-displacement facility.	SC	Store-clock-fast facility.
LS	HFP-significance exception.	SE	Special operation, stack-empty, stack-specification, and stack-type exceptions.
MD	Designation of access registers in the access-register mode is model-dependent.	SF	Special-operation, stack-full, and stack-specification exceptions.
ME	Monitor event.	SI	SI instruction format.
MO	Move-with-optional-specifications facility.	SIY	SIY instruction format.
MS	Message-security assist.	SO	Special-operation exception.
N	Instruction is new in z/Architecture as compared to ESA/390.	SP	Specification exception.
N3	Instruction is new in z/Architecture and has been added to ESA/390.	SQ	HFP-square-root exception.
OP	Operand exception.	SS	SS instruction format.
P	Privileged-operation exception.	SSE	SSE instruction format.
PE	Parsing-enhancement facility.	SSF	SSF instruction format.
PF	PFPO facility.	ST	PER storage-alteration event.
Q	Privileged-operation exception for semiprivililed instructions.	SU	PER store-using-real-address event.
R <sub>1</sub>	R <sub>1</sub> field designates an access register in the access-register mode.	SW	Special-operation exception and space-switch event.
R <sub>2</sub>	R <sub>2</sub> field designates an access register in the access-register mode.	T	Trace exceptions (which include trace table, addressing, and low-address protection).
R <sub>3</sub>	R <sub>3</sub> field designates an access register in the access-register mode.	TF	Decimal-floating-point facility.
RI	RI instruction format.	TR	Decimal-floating-point-rounding facility.
RIE	RIE instruction format.	TS	TOD-clock-steering facility.
RIL	RIL instruction format.	U	Condition code is unpredictable.
		U <sub>1</sub>	R <sub>1</sub> field designates an access register unconditionally.
		U <sub>2</sub>	R <sub>2</sub> field designates an access register unconditionally.
		UB	R <sub>1</sub> and R <sub>3</sub> fields designate access registers unconditionally, and B <sub>2</sub> field designates an access register in the access-register mode.
		UE	HFP unnormalized-extensions facility.
		WE	Space-switch event.

XF	IEEE-exception-simulation facility.
Xg	Simulated IEEE exception.
Xi	IEEE invalid-operation exception.
Xo	IEEE overflow exception.
Xu	IEEE underflow exception.
XX	Execute-extension facility.
Xx	IEEE inexact exception.
Xz	IEEE division-by-zero exception.
Z <sup>1</sup>	Additional exceptions and events for PROGRAM CALL (which include ASX-translation, EX-translation, LX-translation, PC-translation-specification, special-operation, stack-full, and stack-specification exceptions and space-switch event).
Z <sup>2</sup>	Additional exceptions and events for PROGRAM TRANSFER (which include AFX-translation, ASX-translation, primary-authority, and special-operation exceptions and space-switch event).
Z <sup>3</sup>	Additional exceptions for SET SECONDARY ASN (which include AFX translation, ASX translation, secondary authority, and special operation).
Z <sup>4</sup>	Additional exceptions and events for PROGRAM RETURN (which include AFX-translation, ASX-translation, secondary-authority, special-operation, stack-empty, stack-operation, stack-specification, and stack-type exceptions and space-switch event).

## Appendix C. Condition-Code Settings

This appendix lists the condition-code setting for instructions in z/Architecture which set the condition code. In addition to those instructions listed which set the condition code, the condition code may be changed by DIAGNOSE and the target of EXECUTE. The condition code is loaded by LOAD PSW, LOAD PSW EXTENDED, PROGRAM RETURN, RESUME PROGRAM, and SET PROGRAM MASK and by an

interruption. The condition code is set to zero by initial CPU reset and is loaded by the successful conclusion of the initial-program-loading sequence.

Some models may offer instructions which set the condition code and do not appear in this document, such as those provided for assists or as part of special or custom features.

Instruction	Condition Code			
	0	1	2	3
ADD (general)	Zero	< zero	> zero	Overflow
ADD (BFP, DFP)	Zero	< zero	> zero	NaN
ADD DECIMAL	Zero	< zero	> zero	Overflow
ADD HALFWORD	Zero	< zero	> zero	Overflow
ADD HALFWORD IMMEDIATE	Zero	< zero	> zero	Overflow
ADD IMMEDIATE	Zero	< zero	> zero	Overflow
ADD LOGICAL	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL IMMEDIATE	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL WITH CARRY	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL WITH SIGNED IMMEDIATE	—	Not zero, no carry	Zero, carry	Not zero, carry
ADD NORMALIZED	Zero	< zero	> zero	—
ADD UNNORMALIZED	Zero	< zero	> zero	—
AND	Zero	Not zero	—	—
AND IMMEDIATE	Zero	Not zero	—	—
CANCEL SUBCHANNEL	Function initiated	—	—	Not operational
CHECKSUM	Checksum complete	—	—	CPU-determined completion

COMPUTE LAST MESSAGE DIGEST	Normal completion	—	—	Partial completion
COMPUTE MESSAGE AUTHENTICATION CODE	Normal completion	—	—	Partial completion
CONVERT BFP TO HFP	Zero	< zero	> zero	Special case
CONVERT HFP TO BFP	Zero	< zero	> zero	Special case
CONVERT TO FIXED	Zero	< zero	> zero	Special case
CONVERT UTF-16 TO UTF-32	Data processed	Op1 full	Invalid low surrogate	CPU-determined completion
CONVERT UTF-16 TO UTF-8	Data processed	Op1 full	Invalid low surrogate	CPU-determined completion
CONVERT UTF-32 TO UTF-16	Data processed	Op1 full	Invalid Unicode character	CPU-determined completion
CONVERT UTF-32 TO UTF-8	Data processed	Op1 full	Invalid Unicode character	CPU-determined completion
CONVERT UTF-8 TO UTF-16	Data processed	Op1 full	Invalid Unicode character	CPU-determined completion
CONVERT UTF-8 TO UTF-32	Data processed	Op1 full	Invalid d character	CPU-determined completion
DIVIDE TO INTEGER	Remainder complete; normal quotient	Remainder complete; quotient overflow or NaN	Remainder incomplete; normal quotient	Remainder incomplete; quotient overflow or NaN
EDIT	Zero	< zero	> zero	—
EDIT AND MARK	Zero	< zero	> zero	—
EXCLUSIVE OR	Zero	Not zero	—	—
EXCLUSIVE OR IMMEDIATE	Zero	Not zero	—	—
EXTRACT STACKED STATE	Branch state entry	Program-call state entry	—	—
FIND LEFTMOST ONE	No one bit found	—	One bit found	—
HALT SUBCHANNEL	Function initiated	Status-pending with other than intermediate status	Busy	Not operational
INSERT ADDRESS SPACE CONTROL	Primary-space mode	Secondary-space mode	Access-register mode	Home-space mode
INSERT CHARACTERS UNDER MASK	All zeros	First bit one	First bit zero	—

Figure C-1. Summary of Condition-Code Settings

Instruction	Condition Code			
	0	1	2	3
LOAD ADDRESS SPACE PARAMETERS	Parameters loaded	Primary ASN not available	Secondary ASN not available or not authorized	Space-switch event
LOAD AND TEST (general, HFP)	Zero	< zero	> zero	—
LOAD AND TEST (BFP, DFP)	Zero	< zero	> zero	NaN
LOAD COMPLEMENT (gen)	Zero	< zero	> zero	Overflow
LOAD COMPLEMENT (BFP)	Zero	< zero	> zero	NaN
LOAD COMPLEMENT (HFP)	Zero	< zero	> zero	—
LOAD NEGATIVE (gen, HFP)	Zero	< zero	—	—
LOAD NEGATIVE (BFP)	Zero	< zero	—	NaN
LOAD PAGE-TABLE-ENTRY ADDRESS	Translation, STE.P = 0	Translation, STE.P = 1	I bit on in RTE or STE, or enhanced-DAT applies and STE.FC=1	Exception exists
LOAD POSITIVE (gen)	Zero	—	> zero	Overflow
LOAD POSITIVE (BFP)	Zero	—	> zero	NaN
LOAD POSITIVE (HFP)	Zero	—	> zero	—
LOAD REAL ADDRESS	Translation available	ST entry invalid	PT entry invalid	ASCE or entry not available or length violation
MODIFY SUBCHANNEL	SCHIB information placed in subchannel	Status-pending	Busy	Not operational
MOVE LONG	Length equal	Length low	Length high	Destructive overlap
MOVE LONG EXTENDED	Length equal	Length low	Length high	CPU-determined completion
MOVE LONG UNICODE	Length equal	Length low	Length high	CPU-determined completion
MOVE PAGE	Data moved	Operand 1 invalid, both valid in ES, locked, or ES error	Operand 2 invalid	—
MOVE STRING	—	Data moved	—	CPU-determined completion
MOVE TO PRIMARY	Length ≤ 256	—	—	Length > 256
MOVE TO SECONDARY	Length ≤ 256	—	—	Length > 256
MOVE WITH KEY	Length ≤ 256	—	—	Length > 256
MOVE WITH OPTIONAL SPECIFICATIONS OR	Length ≤ 4,096 Zero	— Not zero	—	Length > 4,096 —
OR IMMEDIATE	Zero	Not zero	—	—
PAGE IN	Page-in operation completed	Expanded-storage data error	—	Expanded-storage block not available
PAGE OUT	Page-out operation completed	Expanded-storage data error	—	Expanded-storage block not available
PERFORM FLOATING-POINT OPERATION (test bit zero)	Normal result	Nontrap exception	Trap exception with alternate action	—
PERFORM FLOATING-POINT OPERATION (test bit one)	Function code valid	—	—	Function code invalid
PERFORM LOCKED OPERATION (test bit zero)	Equal	Op1 not equal	Op1 equal, op3 not equal (dcs only)	—
PERFORM LOCKED OPERATION (test bit one)	Function code valid	—	—	Function code invalid
PERFORM TIMING FACILITY FUNCTION	Function performed	—	—	Function not available
PERFORM TOPOLOGY FUNCTION (FC 0 or 1)	Change initiated	—	Request rejected	—
PERFORM TOPOLOGY FUNCTION (FC 2)	Report not pending	Report pending	—	—
RESET CHANNEL PATH	Function initiated	—	Busy	Not operational

Figure C-1. Summary of Condition-Code Settings

Instruction	Condition Code			
	0	1	2	3
RESET REFERENCE BIT EXTENDED	R bit zero, C bit zero	R bit zero, C bit one	R bit one, C bit zero	R bit one, C bit one
RESUME SUBCHANNEL	Function initiated	Status pending	Function not applicable	Not operational
ROTATE THEN AND SELECTED BITS	Zero	Not zero	—	—
ROTATE THEN EXCLUSIVE OR SELECTED BITS	Zero	Not zero	—	—
ROTATE THEN INSERT SELECTED BITS	Zero	< zero	> zero	—
ROTATE THEN OR SELECTED BITS	Zero	Not zero	—	—
SEARCH STRING	—	Found	Not found	CPU-determined completion
SEARCH STRING UNICODE	—	Found	Not found	CPU-determined completion
SET CLOCK	Set	Secure	—	Not operational
SET STORAGE KEY EXTENDED	Storage key not set	Entire storage key set	Partial storage key set	Entire storage key set; bits 48-55 of GR R <sub>1</sub> , unpredictable
SHIFT AND ROUND DECIMAL	Zero	< zero	> zero	Overflow
SHIFT LEFT (DOUBLE/SINGLE)	Zero	< zero	> zero	Overflow
SHIFT RIGHT (DOUBLE/SINGLE)	Zero	< zero	> zero	—
SIGNAL PROCESSOR	Order accepted	Status stored	Busy	Not operational
START SUBCHANNEL	Function initiated	Status-pending	Busy	Not operational
STORE CHANNEL REPORT WORD	CRW stored	Zeros stored	—	—
STORE CLOCK	Set	Not set	Error	Stopped or not operational
STORE CLOCK FAST	Set	Not set	Error	Stopped or not operational
STORE CLOCK EXTENDED	Set	Not set	Error	Stopped or not operational
STORE FACILITY LIST EXTENDED	Complete facility list stored	—	—	Incomplete facility list stored
STORE SUBCHANNEL	SCHIB stored	—	—	Not operational
STORE SYSTEM INFORMATION	Information provided	—	—	Information not available
SUBTRACT (general)	Zero	< zero	> zero	Overflow
SUBTRACT (BFP, DFP)	Zero	< zero	> zero	NaN
SUBTRACT DECIMAL	Zero	< zero	> zero	Overflow
SUBTRACT HALFWORD	Zero	< zero	> zero	Overflow
SUBTRACT LOGICAL	—	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT LOGICAL IMMEDIATE	—	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT LOGICAL WITH BORROW	Zero, borrow	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT NORMALIZED (HFP)	Zero	< zero	> zero	—
SUBTRACT UNNORMALIZED (HFP)	Zero	< zero	> zero	—
TEST ACCESS	ALET 0	DU access list, no exceptions	PS access list, no exceptions	ALET 1 or exceptions
TEST ADDRESSING MODE	Twenty-four bit mode	Thirty-one bit mode	—	Sixty-four bit mode
TEST AND SET	Left bit zero	Left bit one	—	—
TEST BLOCK	Usable	Not usable	—	—
TEST DATA CLASS	Zero (no match)	One (match)	—	—
TEST DATA GROUP	Zero (no match)	One (match)	—	—
TEST DECIMAL	Digits and sign valid	Sign invalid	Digit invalid	Sign and digit invalid

Figure C-1. Summary of Condition-Code Settings

Instruction	Condition Code			
	0	1	2	3
TEST PENDING INTERRUPTION	Interruption code not stored	Interruption code stored	—	—
TEST PROTECTION	Can fetch, can store	Can fetch, cannot store	Cannot fetch, cannot store	Translation not available Not operational
TEST SUBCHANNEL	IRB stored; subchannel status-pending	IRB stored; subchannel not status-pending	—	All ones All ones —
TEST UNDER MASK	All zeros	Mixed	—	All ones
TEST UNDER MASK (HIGH/LOW)	All zeros	Mixed, left bit zero	Mixed, left bit one	All ones
TRANSLATE AND TEST	All zeros	Incomplete	Complete	—
TRANSLATE AND TEST EXTENDED	All zeros	Nonzero code selected	—	CPU-determined completion
TRANSLATE AND TEST REVERSE	All zeros	Incomplete	Complete	—
TRANSLATE AND TEST REVERSE EXTENDED	All zeros	Nonzero code selected	—	CPU-determined completion
TRANSLATE EXTENDED	Data processed	Op1 byte equal test byte	—	CPU-determined completion
TRANSLATE ONE TO ONE, ONE TO TWO, TWO TO ONE, TWO TO TWO	Character equal test character not found	Character equal test character found	—	CPU-determined completion
UNPACK ASCII	Sign plus	Sign minus	—	Sign invalid
UNPACK UNICODE	Sign plus	Sign minus	—	Sign invalid
UPDATE TREE	Equal	Not equal or no comparison	—	GR5 nonzero, GR0 negative
ZERO AND ADD	Zero	< zero	> zero	Overflow

## **Appendix H. Hexadecimal Tables**

The following tables aid in converting hexadecimal values to decimal values, or the reverse.

### ***Direct Conversion Table***

This table provides direct conversion of decimal and hexadecimal numbers in these ranges:

Hexadecimal 000 to FFF	Decimal 0000 to 4095
---------------------------	-------------------------

To convert numbers outside these ranges, and to convert fractions, use the hexadecimal and decimal conversion tables that follow the direct conversion table in this appendix.

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
00_	0000	0001	0002	0003	0004	0005	0006	0007	0008	0009	0010	0011	0012	0013	0014	0015

### TO CONVERT HEXADECIMAL TO DECIMAL

- Locate the column of the decimal numbers corresponding to the leftmost digit or letter of the hexadecimal; select from this column and record the number that corresponds to the position of the hexadecimal digit or letter.
- Repeat step 1 for the next (second from the left) position.
- Repeat step 1 for the units (third from the left) position.
- Add the numbers selected from the table to form the decimal number.

### EXAMPLE

Conversion of  
Hexadecimal Value      D34

1. D	3328
2. 3	48
3. 4	+ 4
4. Decimal	3380

To convert integer numbers greater than the capacity of the table, use the techniques below:

### HEXADECIMAL TO DECIMAL

Successive cumulative multiplication from left to right, adding units position.

$$\text{Example: } D34_{16} = 3380_{10}D = 13$$

$$\begin{array}{r} \times 16 \\ \hline 208 \\ + 3 \\ \hline 211 \\ \times 16 \\ \hline 3376 \\ + 4 \\ \hline 3380 \end{array}$$

### TO CONVERT DECIMAL TO HEXADECIMAL

- (a) Select from the table the highest decimal number that is equal to or less than the number to be converted.  
(b) Record the hexadecimal of the column containing the selected number.  
(c) Subtract the selected decimal from the number to be converted.
- Using the remainder from step 1(c), repeat all of step 1 to develop the second position of the hexadecimal (and a remainder)
- Using the remainder from step 2, repeat all of step 1 to develop the units position of the hexadecimal.
- Combine the terms to form the hexadecimal number.

### EXAMPLE

Conversion of  
Decimal Value      3380

1. D	-3328
2. 3	- 48
3. 4	- 4
4. Hexadecimal	D34

### DECIMAL TO HEXADECIMAL

Divide and collect the remainder in reverse order

$$\text{Example: } 3380_{10} = X_{16}$$

$$\begin{array}{r} \text{Remainder} \\ \uparrow \\ 16 \longdiv{3380} \rightarrow 4 \\ 16 \longdiv{211} \rightarrow 3 \\ 16 \longdiv{13} \rightarrow D \\ 3380_{10} = D34_{16} \end{array}$$

### POWERS OF 16 TABLE

Example:  $268,435,456_{10} = (2.68435456 \times 10^8)_{10} = 1000\ 0000_{16} = (10^7)_{16}$

$16^n$	n
1	0
16	1

### TO CONVERT .ABC HEXADECIMAL TO DECIMAL

Find .A in position 1 .6250  
 Find .0B in position 2 .0429 6825  
 Find .00C in position 3 +.0029 2968 7500  
 .ABC is equal to .6708 9843 7500

To convert fractions beyond the capacity of the table, use techniques below:

### HEXADECIMAL TO FRACTION DECIMAL

Convert the hexadecimal fraction to its decimal equivalent using the same technique as for integer numbers. Divide the results by  $16^n$  (n is the number of fraction positions).

Example:  $.8A7 = .540771_{10}$

$$\begin{array}{r} 8A7_{16} = 2215_{10} \\ \hline 16^3 = 4096 \quad 4096 \overline{)2215.000000} \end{array} .540771$$

### TO CONVERT .13 DECIMAL TO HEXADECIMAL

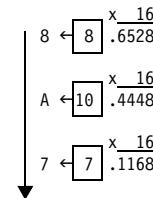

- Find .1250 next lowest to subtract  $\begin{array}{r} .1300 \\ - .1250 \\ \hline \end{array} = .2 \text{ Hex}$
- Find .0039 0625 next lowest to  $\begin{array}{r} .0050 0000 \\ - .0039 0625 \\ \hline \end{array} = .01$
- Find .0009 7656 2500  $\begin{array}{r} .0010 9375 0000 \\ - .0009 7656 2500 \\ \hline \end{array} = .004$
- Find .0001 0681 1523 4375  $\begin{array}{r} .0001 1718 7500 0000 \\ - .0001 0681 1523 4375 \\ \hline \end{array} = .0007$   
 $\begin{array}{r} .0000 1037 5976 5625 \\ - .0000 1037 5976 5625 \\ \hline \end{array} = .2147 \text{ Hex}$
- .13 Decimal is approximately equal to \_\_\_\_\_

### DECIMAL FRACTION TO HEXADECIMAL

Collect integer parts of product in the order of calculation.

Example:  $.5408_{10} = .8A7_{16}$

.5408

### **Hexadecimal Addition and Subtraction Table**

Example:  $6 + 2 = 8$ ,  $8 - 2 = 6$ , and  $8 - 6 = 2$

	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F

 MXR (MULTIPLY) HFP instruction 18-17  
 MxTR (MULTIPLY) DFP instruction 20-33

## N

N (AND) instruction 7-25  
 N condition (I/O) 16-12  
 NaN (not-a-number) 9-2, 19-4, 20-7  
 NC (AND) instruction 7-25  
 near-valid CBC 11-2  
     in storage 11-5  
 negative zero  
     binary 7-4  
     decimal 8-3  
     example A-5  
 new PSW 4-3  
     assigned storage locations for 3-64  
     fetched during interruption 6-2  
 next-entry size (in linkage stack) 5-76  
 NG (AND) instruction 7-25  
 NGR (AND) instruction 7-25  
 NI (AND) instruction 7-25  
     example A-8  
 NIHF (AND IMMEDIATE) instruction 7-26  
 NIHH (AND IMMEDIATE) instruction 7-26  
 NIHL (AND IMMEDIATE) instruction 7-26  
 NILF (AND IMMEDIATE) instruction 7-26

NILH (AND IMMEDIATE) instruction 7-26  
NILL (AND IMMEDIATE) instruction 7-26  
NIY (AND) instruction 7-25  
no-operation  
    instruction (BRANCH ON CONDITION) 7-30  
    instruction (BRANCH RELATIVE ON  
        CONDITION) 7-33  
node (of tree structure) 7-241  
noninterlocked-update storage reference 5-94  
nonnumeric entities  
    decimal 20-7  
    IEEE 9-2  
nontrap action  
    IEEE 9-16  
nonvolatile storage 3-2  
normal numbers  
    class of BFP data 19-4  
    class of DFP data 20-7  
normalization  
    of HFP numbers 18-2  
not-a-number (NaN) 9-2, 19-4, 20-7  
not operational  
    as channel-path state 16-12  
        *See* path-not-operational bit  
    as CPU state 4-61  
    as TOD-clock state 4-38  
not set (TOD-clock state) 4-37  
NR (AND) instruction 7-25  
nullification  
    exceptions to 5-22  
    for exigent machine-check conditions 11-10  
    of instruction execution 5-20  
    of unit of operation 5-21  
numbering  
    of addresses (byte locations) 3-2  
    of bits 3-3  
numbers  
    binary 7-3  
        examples A-2  
    binary-floating-point 19-2  
    CPU-model 10-120  
    decimal 8-1  
        examples A-4  
    device 13-5  
    hexadecimal 5-6  
    hexadecimal-floating-point 18-3  
        examples A-5  
    machine-type 10-120  
numeric bits 8-1  
    moving of 7-174  
Numeric part of PC number 5-79  
NY (AND) instruction 7-25

**O**

**TRANSLATE ONE TO ONE** instruction 7-234  
**TRANSLATE ONE TO TWO** instruction 7-234  
**TRANSLATE TWO TO ONE** instruction 7-234  
**TRANSLATE TWO TO TWO** instruction 7-234  
 translation  
 address 3-34  
*See* dynamic address translation  
 exception identification 3-62  
 lookaside buffer  
*See* TLB  
 PC-number 5-30  
 specification exception 6-39  
 tables for 3-40  
 translation modes 3-36  
 translation parameters 3-36  
 translation path 3-53  
 trap action  
     IEEE 9-16  
 trap control block 10-151  
**TRAP** instruction 10-150  
 trap save area 10-151  
**TRAP2 (TRAP)** instruction 10-150  
**TRAP4 (TRAP)** instruction 10-150  
**TRE (TRANSLATE EXTENDED)** instruction 7-231  
 tree structure for sorting 7-241  
 example A-53  
 trial execution  
     for editing instructions and **TRANSLATE** instruction 5-23  
     for PER 4-25  
 trimodal addressing 5-8, 7-7  
**TROO (TRANSLATE ONE TO ONE)** instruction 7-234  
**TROT (TRANSLATE ONE TO TWO)** instruction 7-234  
**TRT (TRANSLATE AND TEST)** instruction 7-225  
 example A-34  
**TRTO (TRANSLATE TWO TO ONE)** instruction 7-234  
**TRTR (TRANSLATE AND TEST REVERSE)** instruction 7-231  
**TRTT (TRANSLATE TWO TO TWO)** instruction 7-234  
 true zero (HFP number) 18-1  
**TS (TEST AND SET)** instruction 7-223

**TSCH (TEST SUBCHANNEL)** instruction 14-20  
 two's complement binary notation 7-4  
     examples A-2  
 type of **PROGRAM CALL** 5-34

## U

ulp (unit in the last place) 9-7, 9-8, 19-3  
 underflow  
*See* exponent underflow  
 unit check (device status)  
     in establishing dedicated allegiance 15-12  
 unit of operation 5-20  
 unlock A-47  
     example with FIFO queuing A-50  
     example with LIFO queuing A-49  
 unnormalized floating-point number 18-3  
     HFP data only 9-3  
 unordered (comparison to a NaN) 9-21  
**UNPACK ASCII** instruction 7-239  
**UNPACK** instruction 7-238  
     example A-35  
**UNPACK UNICODE** instruction 7-240  
**UNPK (UNPACK)** instruction 7-238  
     example A-35  
**UNPKA (PACK ASCII)** instruction 7-239  
**UNPKU (PACK UNICODE)** instruction 7-240  
 unprivileged instructions 4-5, 7-3  
 unsigned binary  
     arithmetic 7-5  
     integer 7-3  
         examples A-3  
         in address generation 5-9  
 unsigned-packed-decimal format 8-2  
     used in DFP formatting instructions 20-8  
 unsigned scaling exponent ( $\alpha$ ) 9-12  
 unsolicited interruption condition (I/O) 16-3  
 unstack-suppression bit 5-75  
 unstacking process 5-82  
 update reference 5-93  
**UPDATE TREE** instruction 7-241  
     example A-53  
**UPT (UPDATE TREE)** instruction 7-241  
     example A-53  
 usable ALB entry 5-61  
**UTC (Coordinated Universal Time)** used in TOD epoch 4-40

## V

valid ART-table entry 5-61  
 valid CBC 11-2  
 valid floating-point-register numbers 9-9  
 valid region-table, segment-table, or page-table entry 3-53

validation 11-5  
of registers 11-8  
of storage 11-6  
of storage key 11-7  
of TOD clock 11-8  
validity bit for backward stack-entry address 5-76  
validity bit for forward-section-header address 5-77  
validity bits  
  in machine-check-interruption code 11-19  
  in subchannel logout 16-35  
variable-length field 3-3  
version code 10-120  
view (of floating-point numbers) 9-2  
  common-rounding-point 9-13  
  fraction 9-2  
  left-units view 9-2  
  right-units view 9-2  
virtual address 3-5  
virtual machine  
  extensions for 1-19  
virtual storage 3-34  
VM-data-space facility 1-19  
volatile storage 3-2  
  effect of power-on reset on 4-54  
voting digit 9-13  
VTAM use of symbol translation 7-97

## W

wait indicator 12-6  
wait-state bit  
  in PSW 4-5  
warning (machine-check condition) 11-16  
  subclass-mask bit for 11-24  
word 3-3  
word-concurrent storage references 5-96  
working allegiance (I/O) 15-11  
wraparound  
  of instruction addresses 5-8  
  of PER addresses 4-30  
  of register numbers  
    for LOAD MULTIPLE instruction 7-159  
    for STORE MULTIPLE instruction 7-218  
of storage addresses 3-7  
  controlled by addressing mode 3-6  
  for MOVE INVERSE instruction 7-164  
  for MOVE LONG EXTENDED instruction  
    7-169  
  for MOVE LONG instruction 7-165  
  for MOVE LONG UNICODE instruction 7-173

for MOVE WITH OPTIONAL  
SPECIFICATIONS instruction 10-59  
of TOD clock 4-37

## X

X (EXCLUSIVE OR) instruction 7-142  
X field of instruction 5-8  
XA (extended architecture)  
  See 370-XA architecture  
XC (EXCLUSIVE OR) instruction 7-142  
  examples A-20  
XG (EXCLUSIVE OR) instruction 7-142  
XGR (EXCLUSIVE OR) instruction 7-142  
XI (EXCLUSIVE OR) instruction 7-142  
  example A-21  
XIHF (EXCLUSIVE OR IMMEDIATE) instruction  
  7-143  
XILF (EXCLUSIVE OR IMMEDIATE) instruction  
  7-143  
XIY (EXCLUSIVE OR) instruction 7-142  
XR (EXCLUSIVE OR) instruction 7-142  
XSCH (CANCEL SUBCHANNEL) instruction 14-4  
XY (EXCLUSIVE OR) instruction 7-142

## Z

Z bit (zero condition-code bit) 16-11  
  as cause of intermediate interruption condition  
  16-17  
z/Architecture architecture  
  additions to 1-1, 1-7  
  original highlights of 1-1  
ZAP (ZERO AND ADD) instruction 8-13  
  example A-41  
zero  
  instruction-length code 6-6  
  negative  
    See negative zero  
  normal meaning for byte value xxiii  
  setting floating-point register to 9-31  
  true (HFP number) 18-1  
ZERO AND ADD instruction 8-13  
  example A-41  
zero condition code (Z bit in SCSW) 16-11  
zone bits 8-1  
  moving of 7-177  
zoned decimal numbers 8-1  
zoned-decimal numbers  
  examples A-4

# **Communicating Your Comments to IBM**

z/Architecture Principles of Operation

Publication No. SA22-7832-06

If you especially like or dislike anything about this book, please use one of the methods listed below to send your comments to IBM. Whichever method you choose, make sure you send your name, address, and telephone number if you would like a reply.

Feel free to comment on specific errors or omissions, accuracy, organization, subject matter, or completeness of this book. However, the comments you send should pertain to only the information in this manual and the way in which the information is presented. To request additional publications, or to ask questions or make comments about the functions of IBM products or systems, you should talk to your IBM representative or to your IBM authorized remarketer.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you.

If you are mailing a reader's comment form (RCF) from a country other than the United States, you can give the RCF to the local IBM branch office or IBM representative for postage-paid mailing.

- If you prefer to send comments by mail, use the RCF at the back of this book.
- If you prefer to send comments by FAX, use this number:
  - FAX: (International Access Code)+1+845+432-9405
- If you prefer to send comments electronically, use one of these network IDs:
  - Internet e-mail: mhvrccfs@us.ibm.com
  - World Wide Web: <http://www.ibm.com/servers/eserver/zseries/zos/webqs.html>

Make sure to include the following in your note:

- Title and publication number of this book
- Page number or topic to which your comment applies

Optionally, if you include your telephone number, we will be able to respond to your comments by phone.

# Reader's Comments — We'd Like to Hear from You

## **z/Architecture Principles of Operation**

### **Publication No. SA22-7832-06**

You may use this form to communicate your comments about this publication, its organization, or subject matter, with the understanding that IBM may use or distribute whatever information you supply in any way it believes appropriate without incurring any obligation to you. Your comments will be sent to the author's department for whatever review and action, if any, are deemed appropriate.

**Note:** Copies of IBM publications are not stocked at the location to which this form is addressed. Please direct any requests for copies of publications, or for assistance in using your IBM system, to your IBM representative or to the IBM branch office serving your locality.
